- With `negbin` then if ‘performance iteration’ is used for smoothing parameter estimation (see `gam`), then smoothing parameters are chosen by GCV and theta is chosen in order to ensure that the Pearson estimate of the scale parameter is as close as possible to 1, the value that the scale parameter should have.
- If ‘outer iteration’ is used for smoothing parameter selection with the `nb` family then theta is estimated alongside the smoothing parameters by ML or REML.

To use the first option, set the optimizer argument of `gam` to “perf” (it can sometimes fail to converge).

**Usage**

```
negbin(theta = stop("'theta' must be specified"), link = "log")
nb(theta = NULL, link = "log")
```

**Arguments**

|       |   |
|-------|---|
| theta | Either i) a single value known value of theta or ii) two values of theta specifying the endpoints of an interval over which to search for theta (this is an option only for <code>negbin</code> ). For <code>nb</code> then a positive supplied theta is treated as a fixed known parameter, otherwise it is estimated (the absolute value of a negative theta is taken as a starting value). |
| link  | The link function: one of “log”, “identity” or “sqrt”   |

**Details**

`nb` allows estimation of the theta parameter alongside the model smoothing parameters, but is only useable with `gam` (not `bam` or `gamm`).

For `negbin`, if a single value of theta is supplied then it is always taken as the known fixed value and this is useable with `bam` and `gamm`. If theta is two numbers (`theta[2]>theta[1]`) then they are taken as specifying the range of values over which to search for the optimal theta. This option should only be used with performance iteration estimation (see `gam` argument `optimizer`), in which case the method of estimation is to choose  $\hat{\theta}$  so that the GCV (Pearson) estimate of the scale parameter is one (since the scale parameter is one for the negative binomial). In this case  $\theta$  estimation is nested within the IRLS loop used for GAM fitting. After each call to fit an iteratively weighted additive model to the IRLS pseudodata, the  $\theta$  estimate is updated. This is done by conditioning on all components of the current GCV/Pearson estimator of the scale parameter except  $\theta$  and then searching for the  $\theta$  which equates this conditional estimator to one. The search is a simple bisection search after an initial crude line search to bracket one. The search will terminate at the upper boundary of the search region is a Poisson fit would have yielded an estimated scale parameter  $<1$ .

**Value**

For negbin an object inheriting from class family, with additional elements

|          |  |
|----------|--|
| dvar     | the function giving the first derivative of the variance function w.r.t. $\mu$ .   |
| d2var    | the function giving the second derivative of the variance function w.r.t. $\mu$ .  |
| getTheta | A function for retrieving the value(s) of theta. This also useful for retriving the estimate of theta after fitting (see example). |

For nb an object inheriting from class extended.family.

**WARNINGS**

`gamm` and `bam` do not support theta estimation

The negative binomial functions from the MASS library are no longer supported.

          optimizer="perf",data=dat)
plot(b1,pages=1)
print(b1)
```

```
## another example...
set.seed(1)
f <- dat$f
f <- f - min(f)+5; g <- f^2/10
dat$y <- rnbino(m(g, size=3, mu=g))
b2 <- gam(y~s(x0)+s(x1)+s(x2)+s(x3), family=nb(link="sqrt"),
          data=dat, method="REML")
plot(b2, pages=1)
print(b2)
rm(dat)
```

---

new.name

---

*Obtain a name for a new variable that is not already in use*

---

## Description

[gamm](#) works by transforming a GAMM into something that can be estimated by [lme](#), but this involves creating new variables, the names of which should not clash with the names of other variables on which the model depends. This simple service routine checks a suggested name against a list of those in use, and if necessary modifies it so that there is no clash.

## Usage

```
new.name(proposed, old.names)
```

## Arguments

|           |   |
|-----------|---|
| proposed  | a suggested name                              |
| old.names | An array of names that must not be duplicated |

## Value

A name that is not in old.names.

## Author(s)

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

## References

[gamm](#)

## Examples

```
require(mgcv)
old <- c("a", "tuba", "is", "tubby")
new.name("tubby", old)
```

## Description

It is common practice in statistical optimization to use log-parameterizations when a parameter ought to be positive. i.e. if an optimization parameter  $a$  should be non-negative then we use  $a = \exp(b)$  and optimize with respect to the unconstrained parameter  $b$ . This often works well, but it does imply a rather limited working range for  $b$ : using 8 byte doubles, for example, if  $b$ 's magnitude gets much above 700 then  $a$  overflows or underflows. This can cause problems for numerical optimization methods.

notExp is a monotonic function for mapping the real line into the positive real line with much less extreme underflow and overflow behaviour than exp. It is a piece-wise function, but is continuous to second derivative: see the source code for the exact definition, and the example below to see what it looks like.

notLog is the inverse function of notExp.

The major use of these functions was originally to provide more robust pdMat classes for lme for use by [gamm](#). Currently the [notExp2](#) and [notLog2](#) functions are used in their place, as a result of changes to the nlme optimization routines.

## Usage

```
notExp(x)
```

```
notLog(x)
```

## Arguments

**x**                      Argument array of real numbers (notExp) or positive real numbers (notLog).

## Value

An array of function values evaluated at the supplied argument values.

## Author(s)

## Examples

```
## Illustrate the notExp function:
## less steep than exp, but still monotonic.
require(mgcv)
x <- -100:100/10
op <- par(mfrow=c(2,2))
plot(x,notExp(x),type="l")
lines(x,exp(x),col=2)
plot(x,log(notExp(x)),type="l")
lines(x,log(exp(x)),col=2) # redundancy intended
x <- x/4
plot(x,notExp(x),type="l")
lines(x,exp(x),col=2)
plot(x,log(notExp(x)),type="l")
lines(x,log(exp(x)),col=2) # redundancy intended
par(op)
range(notLog(notExp(x))-x) # show that inverse works!
```

notExp2

*Alternative to log parameterization for variance components*

## Description

notLog2 and notExp2 are alternatives to log and exp or [notLog](#) and [notExp](#) for re-parameterization of variance parameters. They are used by the [pdTens](#) and [pdIdnot](#) classes which in turn implement smooths for [gamm](#).

The functions are typically used to ensure that smoothing parameters are positive, but the notExp2 is not monotonic: rather it cycles between ‘effective zero’ and ‘effective infinity’ as its argument changes. The notLog2 is the inverse function of the notExp2 only over an interval centered on zero.

Parameterizations using these functions ensure that estimated smoothing parameters remain positive, but also help to ensure that the likelihood is never indefinite: once a working parameter pushes a smoothing parameter below ‘effective zero’ or above ‘effective infinity’ the cyclic nature of the notExp2 causes the likelihood to decrease, where otherwise it might simply have flattened.

This parameterization is really just a numerical trick, in order to get lme to fit gamm models, without failing due to indefiniteness. Note in particular that asymptotic results on the likelihood/REML criterion are not invalidated by the trick, unless parameter estimates end up close to the effective zero or effective infinity: but if this is the case then the asymptotics would also have been invalid for a conventional monotonic parameterization.

This reparameterization was made necessary by some modifications to the underlying optimization method in lme introduced in nlme 3.1-62. It is possible that future releases will return to the [notExp](#) parameterization.

Note that you can reset ‘effective zero’ and ‘effective infinity’: see below.

## Usage

```
notExp2(x,d=.Options$mgcv.vc.logrange,b=1/d)
```

```
notLog2(x,d=.Options$mgcv.vc.logrange,b=1/d)
```

**Arguments**

|   |  |
|---|--|
| x | Argument array of real numbers (notExp) or positive real numbers (notLog).   |
| d | the range of notExp2 runs from $\exp(-d)$ to $\exp(d)$ . To change the range used by gamm reset mgcv.vc.logrange using <a href="#">options</a> . |
| b | determines the period of the cycle of notExp2.   |

**Value**

An array of function values evaluated at the supplied argument values.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

---

null.space.dimension    *The basis of the space of un-penalized functions for a TPRS*

---

**Description**

The thin plate spline penalties give zero penalty to some functions. The space of these functions is spanned by a set of polynomial terms. null.space.dimension finds the dimension of this space,  $M$ , given the number of covariates that the smoother is a function of,  $d$ , and the order of the smoothing penalty,  $m$ . If  $m$  does not satisfy  $2m > d$  then the smallest possible dimension for the null space is found given  $d$  and the requirement that the smooth should be visually smooth.

**Usage**

```
null.space.dimension(d,m)
```

**Arguments**

|                |   |
|----------------|---|
| <code>d</code> | is a positive integer - the number of variables of which the t.p.s. is a function.                                      |
| <code>m</code> | a non-negative integer giving the order of the penalty functional, or signalling that the default order should be used. |

**Details**

Thin plate splines are only visually smooth if the order of the wiggleness penalty,  $m$ , satisfies  $2m > d + 1$ . If  $2m < d + 1$  then this routine finds the smallest  $m$  giving visual smoothness for the given  $d$ , otherwise the supplied  $m$  is used. The null space dimension is given by:

$$M = (m + d - 1)! / (d!(m - 1)!)$$

which is the value returned.

**Value**

An integer (array), the null space dimension  $M$ .

```

---

ocat

*GAM ordered categorical family*

---

**Description**

Family for use with [gam](#), implementing regression for ordered categorical data. A linear predictor provides the expected value of a latent variable following a logistic distribution. The probability of this latent variable lying between certain cut-points provides the probability of the ordered categorical variable being of the corresponding category. The cut-points are estimated along side the model smoothing parameters (using the same criterion). The observed categories are coded 1, 2, 3, ... up to the number of categories.

**Usage**

```
ocat(theta=NULL,link="identity",R=NULL)
```

## Arguments

|                    |   |
|--------------------|---|
| <code>theta</code> | cut point parameter vector (dimension $R-2$ ). If supplied and all positive, then taken to be the cut point increments (first cut point is fixed at -1). If any are negative then absolute values are taken as starting values for cutpoint increments. |
| <code>link</code>  | The link function: only "identity" allowed at present (possibly for ever).  |
| <code>R</code>     | the number of categories.   |

## Details

Such cumulative threshold models are only identifiable up to an intercept, or one of the cut points. Rather than remove the intercept, `ocat` simply sets the first cut point to -1. Use `predict.gam` with `type="response"` to get the predicted probabilities in each category.

## Value

An object of class `extended.family`.

one.se.rule

---

*The one standard error rule for smoother models*

---

## Description

The ‘one standard error rule’ (see e.g. Hastie, Tibshirani and Friedman, 2009) is a way of producing smoother models than those directly estimated by automatic smoothing parameter selection methods. In the single smoothing parameter case, we select the largest smoothing parameter within one standard error of the optimum of the smoothing parameter selection criterion. This approach can be generalized to multiple smoothing parameters estimated by REML or ML.

## Details

Under REML or ML smoothing parameter selection an asymptotic distributional approximation is available for the log smoothing parameters. Let  $\rho$  denote the log smoothing parameters that we want to increase to obtain a smoother model. The large sample distribution of the estimator of  $\rho$  is  $N(\rho, V)$  where  $V$  is the matrix returned by [sp.vcov](#). Drop any elements of  $\rho$  that are already at ‘effective infinity’, along with the corresponding rows and columns of  $V$ . The standard errors of the log smoothing parameters can be obtained from the leading diagonal of  $V$ . Let the vector of these be  $d$ . Now suppose that we want to increase the estimated log smoothing parameters by an amount  $\alpha d$ . We choose  $\alpha$  so that  $\alpha d^T V^{-1} d = \sqrt{2p}$ , where  $p$  is the dimension of  $d$  and  $2p$  the variance of a chi-squared r.v. with  $p$  degrees of freedom.

The idea is that we increase the log smoothing parameters in proportion to their standard deviation, until the RE/ML is increased by 1 standard deviation according to its asymptotic distribution.

pcls

*Penalized Constrained Least Squares Fitting*

## Description

Solves least squares problems with quadratic penalties subject to linear equality and inequality constraints using quadratic programming.

## Usage

pcls(M)

## Arguments

- M** is the single list argument to pcls. It should have the following elements:
- y** The response data vector.
  - w** A vector of weights for the data (often proportional to the reciprocal of the variance).
  - X** The design matrix for the problem, note that ncol(M\$X) must give the number of model parameters, while nrow(M\$X) should give the number of data.
  - C** Matrix containing any linear equality constraints on the problem (e.g.  $\mathbf{Cp} = \mathbf{c}$ ). If you have no equality constraints initialize this to a zero by zero matrix. Note that there is no need to supply the vector  $\mathbf{c}$ , it is defined implicitly by the initial parameter estimates  $\mathbf{p}$ .
  - S** A list of penalty matrices.  $S[[i]]$  is the smallest contiguous matrix including all the non-zero elements of the  $i$ th penalty matrix. The first parameter it penalizes is given by  $\text{off}[i]+1$  (starting counting at 1).
  - off** Offset values locating the elements of M\$S in the correct location within each penalty coefficient matrix. (Zero offset implies starting in first location)
  - sp** An array of smoothing parameter estimates.
  - p** An array of feasible initial parameter estimates - these must satisfy the constraints, but should avoid satisfying the inequality constraints as equality constraints.
  - Ain** Matrix for the inequality constraints  $\mathbf{A}_{in}\mathbf{p} > \mathbf{b}_{in}$ .
  - bin** vector in the inequality constraints.

## Details

This solves the problem:

$$\text{minimise } \|\mathbf{W}^{1/2}(\mathbf{X}\mathbf{p} - \mathbf{y})\|^2 + \sum_{i=1}^m \lambda_i \mathbf{p}' \mathbf{S}_i \mathbf{p}$$

subject to constraints  $\mathbf{C}\mathbf{p} = \mathbf{c}$  and  $\mathbf{A}_{in}\mathbf{p} > \mathbf{b}_{in}$ , w.r.t.  $\mathbf{p}$  given the smoothing parameters  $\lambda_i$ .  $\mathbf{X}$  is a design matrix,  $\mathbf{p}$  a parameter vector,  $\mathbf{y}$  a data vector,  $\mathbf{W}$  a diagonal weight matrix,  $\mathbf{S}_i$  a positive semi-definite matrix of coefficients defining the  $i$ th penalty and  $\mathbf{C}$  a matrix of coefficients defining the linear equality constraints on the problem. The smoothing parameters are the  $\lambda_i$ . Note that  $\mathbf{X}$  must be of full column rank, at least when projected into the null space of any equality constraints.  $\mathbf{A}_{in}$  is a matrix of coefficients defining the inequality constraints, while  $\mathbf{b}_{in}$  is a vector involved in defining the inequality constraints.

Quadratic programming is used to perform the solution. The method used is designed for maximum stability with least squares problems: i.e.  $\mathbf{X}'\mathbf{X}$  is not formed explicitly. See Gill et al. 1981.

## Value

The function returns an array containing the estimated parameter vector.

plot(b) ## original fit
b$coefficients <- p
plot(b) ## constrained fit
## note that standard errors in preceding plot are obtained from
## unconstrained fit

```

---

pdIdnot

---

*Overflow proof pdMat class for multiples of the identity matrix*

---

## Description

This set of functions is a modification of the pdMat class pdIdent from library nlme. The modification is to replace the log parameterization used in pdMat with a [notLog2](#) parameterization, since the latter avoids indefiniteness in the likelihood and associated convergence problems: the parameters also relate to variances rather than standard deviations, for consistency with the [pdTens](#) class. The functions are particularly useful for working with Generalized Additive Mixed Models where variance parameters/smoothing parameters can be very large or very small, so that overflow or underflow can be a problem.

These functions would not normally be called directly, although unlike the [pdTens](#) class it is easy to do so.

**Usage**

```
pdIdnot(value = numeric(0), form = NULL,  
        nam = NULL, data = sys.frame(sys.parent()))
```

**Arguments**

|       |  |
|-------|--|
| value | Initialization values for parameters. Not normally used.     |
| form  | A one sided formula specifying the random effects structure. |
| nam   | a names argument, not normally used with this class.         |
| data  | data frame in which to evaluate formula.                     |

**Details**

The following functions are provided: `Dim.pdIndot`, `coef.pdIdnot`, `corMatrix.pdIdnot`, `logDet.pdIdnot`, `pdConstruct.pdIdnot`, `pdFactor.pdIdnot`, `pdMatrix.pdIdnot`, `solve.pdIdnot`, `summary.pdIdnot`. (e.g. `mgcv::coef.pdIdnot` to access.)

Note that while the `pdFactor` and `pdMatrix` functions return the inverse of the scaled random effect covariance matrix or its factor, the `pdConstruct` function is initialised with estimates of the scaled covariance matrix itself.

**Value**

A class `pdIdnot` object, or related quantities. See the `nlme` documentation for further details.

**Author(s)**

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

**References**

The nlme source code.

<http://www.maths.bris.ac.uk/~sw15190/>

**See Also**

[te](#), [pdTens](#), [notLog2](#), [gamm](#)

**Examples**

```
# see gamm
```

**Description**

This set of functions implements an nlme library pdMat class to allow tensor product smooths to be estimated by lme as called by gamm. Tensor product smooths have a penalty matrix made up of a weighted sum of penalty matrices, where the weights are the smoothing parameters. In the mixed model formulation the penalty matrix is the inverse of the covariance matrix for the random effects of a term, and the smoothing parameters (times a half) are variance parameters to be estimated. It's not possible to transform the problem to make the required random effects covariance matrix look like one of the standard pdMat classes: hence the need for the pdTens class. A [notLog2](#) parameterization ensures that the parameters are positive.

These functions (pdTens, pdConstruct.pdTens, pdFactor.pdTens, pdMatrix.pdTens, coef.pdTens and summary.pdTens) would not normally be called directly.

**Usage**

```
pdTens(value = numeric(0), form = NULL,
       nam = NULL, data = sys.frame(sys.parent()))
```

**Arguments**

|       |  |
|-------|--|
| value | Initialization values for parameters. Not normally used.   |
| form  | A one sided formula specifying the random effects structure. The formula should have an attribute S which is a list of the penalty matrices the weighted sum of which gives the inverse of the covariance matrix for these random effects. |
| nam   | a names argument, not normally used with this class.   |
| data  | data frame in which to evaluate formula.   |

**Details**

If using this class directly note that it is worthwhile scaling the S matrices to be of 'moderate size', for example by dividing each matrix by its largest singular value: this avoids problems with lme defaults ([smooth.construct.tensor.smooth.spec](#) does this automatically).

This appears to be the minimum set of functions required to implement a new pdMat class.

Note that while the pdFactor and pdMatrix functions return the inverse of the scaled random effect covariance matrix or its factor, the pdConstruct function is sometimes initialised with estimates of the scaled covariance matrix, and sometimes intialized with its inverse.

**Value**

A class pdTens object, or its coefficients or the matrix it represents or the factor of that matrix. pdFactor returns the factor as a vector (packed column-wise) (pdMatrix always returns a matrix).

**Author(s)**

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

```

---

|         |   |
|---------|---|
| pen.edf | <i>Extract the effective degrees of freedom associated with each penalty in a gam fit</i> |
|---------|---|

---

## Description

Finds the coefficients penalized by each penalty and adds up their effective degrees of freedom. Very useful for [t2](#) terms, but hard to interpret for terms where the penalties penalize overlapping sets of parameters (e.g. [te](#) terms).

## Usage

```
pen.edf(x)
```

## Arguments

x                      an object inheriting from gam

## Details

Useful for models containing [t2](#) terms, since it splits the EDF for the term up into parts due to different components of the smooth. This is useful for figuring out which interaction terms are actually needed in a model.

## Value

A vector of EDFs, named with labels identifying which penalty each EDF relates to.

## Author(s)

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

## See Also

[t2](#)

## Examples

```
require(mgcv)
set.seed(20)
dat <- gamSim(1,n=400,scale=2) ## simulate data
## following `t2' smooth basically separates smooth
## of x0,x1 into main effects + interaction...

b <- gam(y~t2(x0,x1,bs="tp",m=1,k=7)+s(x2)+s(x3),
        data=dat,method="ML")
pen.edf(b)

## label "rr" indicates interaction edf (range space times range space)
## label "nr" (null space for x0 times range space for x1) is main
##      effect for x1.
## label "rn" is main effect for x0
## clearly interaction is negligible

## second example with higher order marginals.

b <- gam(y~t2(x0,x1,bs="tp",m=2,k=7,full=TRUE)
        +s(x2)+s(x3),data=dat,method="ML")
pen.edf(b)

## In this case the EDF is negligible for all terms in the t2 smooth
## apart from the 'main effects' (r2 and 2r). To understand the labels
## consider the following 2 examples...
## "r1" relates to the interaction of the range space of the first
##      marginal smooth and the first basis function of the null
##      space of the second marginal smooth
## "2r" relates to the interaction of the second basis function of
##      the null space of the first marginal smooth with the range
##      space of the second marginal smooth.
```

---

place.knots

*Automatically place a set of knots evenly through covariate values*

---

## Description

Given a univariate array of covariate values, places a set of knots for a regression spline evenly through the covariate values.

## Usage

```
place.knots(x,nk)
```

## Arguments

|    |  |
|----|--|
| x  | array of covariate values (need not be sorted).  |
| nk | integer indicating the required number of knots. |

**Details**

Places knots evenly throughout a set of covariates. For example, if you had 11 covariate values and wanted 6 knots then a knot would be placed at the first (sorted) covariate value and every second (sorted) value thereafter. With less convenient numbers of data and knots the knots are placed within intervals between data in order to achieve even coverage, where even means having approximately the same number of data between each pair of knots.

**Value**

An array of knot locations.

x<-runif(30)
place.knots(x,7)
rm(x)
```

---

plot.gam

---

*Default GAM plotting*

---

**Description**

Takes a fitted gam object produced by `gam()` and plots the component smooth functions that make it up, on the scale of the linear predictor. Optionally produces term plots for parametric model components as well.

**Usage**

```
## S3 method for class 'gam'
plot(x,residuals=FALSE,rug=TRUE,se=TRUE,pages=0,select=NULL,scale=-1,
     n=100,n2=40,pers=FALSE,theta=30,phi=30,jit=FALSE,xlab=NULL,
     ylab=NULL,main=NULL,ylim=NULL,xlim=NULL,too.far=0.1,
     all.terms=FALSE,shade=FALSE,shade.col="gray80",shift=0,
     trans=I,seWithMean=FALSE,unconditional=FALSE,by.resids=FALSE,
     scheme=0,...)
```

**Arguments**

|                        |  |
|------------------------|--|
| <code>x</code>         | a fitted gam object as produced by <code>gam()</code> .  |
| <code>residuals</code> | If TRUE then partial residuals are added to plots of 1-D smooths. If FALSE then no residuals are added. If this is an array of the correct length then it is used as the array of residuals to be used for producing partial residuals. If TRUE then the residuals are the working residuals from the IRLS iteration weighted by the IRLS weights. Partial residuals for a smooth term are the residuals that would be obtained by dropping the term concerned from the model, while leaving all other estimates fixed (i.e. the estimates for the term plus the residuals). |
| <code>rug</code>       | when TRUE (default) then the covariate to which the plot applies is displayed as a rug plot at the foot of each plot of a 1-d smooth, and the locations of the covariates are plotted as points on the contour plot representing a 2-d smooth. Setting to FALSE will speed up plotting for large datasets.   |
| <code>se</code>        | when TRUE (default) upper and lower lines are added to the 1-d plots at 2 standard errors above and below the estimate of the smooth being plotted while for 2-d plots, surfaces at +1 and -1 standard errors are contoured and overlayed on the contour plot for the estimate. If a positive number is supplied then this number is multiplied by the standard errors when calculating standard error curves or surfaces. See also <code>shade</code> , below.  |
| <code>pages</code>     | (default 0) the number of pages over which to spread the output. For example, if <code>pages=1</code> then all terms will be plotted on one page with the layout performed automatically. Set to 0 to have the routine leave all graphics settings as they are.  |
| <code>select</code>    | Allows the plot for a single model term to be selected for printing. e.g. if you just want the plot for the second smooth term set <code>select=2</code> .   |
| <code>scale</code>     | set to -1 (default) to have the same y-axis scale for each plot, and to 0 for a different y axis for each plot. Ignored if <code>ylim</code> supplied.   |
| <code>n</code>         | number of points used for each 1-d plot - for a nice smooth plot this needs to be several times the estimated degrees of freedom for the smooth. Default value 100.  |
| <code>n2</code>        | Square root of number of points used to grid estimates of 2-d functions for contouring.  |
| <code>pers</code>      | Set to TRUE if you want perspective plots for 2-d terms.   |
| <code>theta</code>     | One of the perspective plot angles.  |
| <code>phi</code>       | The other perspective plot angle.  |
| <code>jitter</code>    | Set to TRUE if you want rug plots for 1-d terms to be jittered.  |
| <code>xlab</code>      | If supplied then this will be used as the x label for all plots.   |
| <code>ylab</code>      | If supplied then this will be used as the y label for all plots.   |
| <code>main</code>      | Used as title (or z axis label) for plots if supplied.   |
| <code>ylim</code>      | If supplied then this pair of numbers are used as the y limits for each plot.  |
| <code>xlim</code>      | If supplied then this pair of numbers are used as the x limits for each plot.  |
| <code>too.far</code>   | If greater than 0 then this is used to determine when a location is too far from data to be plotted when plotting 2-D smooths. This is useful since smooths tend to go wild away from data. The data are scaled into the unit square before deciding what to exclude, and <code>too.far</code> is a distance within the unit square. Setting to zero can make plotting faster for large datasets, but care then needed with interpretation of plots.   |

|                            |  |
|----------------------------|--|
| <code>all.terms</code>     | if set to TRUE then the partial effects of parametric model components are also plotted, via a call to <a href="#">termplot</a> . Only terms of order 1 can be plotted in this way.  |
| <code>shade</code>         | Set to TRUE to produce shaded regions as confidence bands for smooths (not available for parametric terms, which are plotted using <a href="#">termplot</a> ).   |
| <code>shade.col</code>     | define the color used for shading confidence bands.  |
| <code>shift</code>         | constant to add to each smooth (on the scale of the linear predictor) before plotting. Can be useful for some diagnostics, or with <code>trans</code> .  |
| <code>trans</code>         | function to apply to each smooth (after any shift), before plotting. <code>shift</code> and <code>trans</code> are occasionally useful as a means for getting plots on the response scale, when the model consists only of a single smooth.  |
| <code>seWithMean</code>    | if TRUE the component smooths are shown with confidence intervals that include the uncertainty about the overall mean. If FALSE then the uncertainty relates purely to the centred smooth itself. Marra and Wood (2012) suggests that TRUE results in better coverage performance, and this is also suggested by simulation. |
| <code>unconditional</code> | if TRUE then the smoothing parameter uncertainty corrected covariance matrix is used to compute uncertainty bands, if available. Otherwise the bands treat the smoothing parameters as fixed.  |
| <code>by.resids</code>     | Should partial residuals be plotted for terms with by variables? Usually the answer is no, they would be meaningless.  |
| <code>scheme</code>        | Integer or integer vector selecting a plotting scheme for each plot. See details.  |
| <code>...</code>           | other graphics parameters to pass on to plotting commands. See details for smooth plot specific options.   |

## Details

Produces default plot showing the smooth components of a fitted GAM, and optionally parametric terms as well, when these can be handled by [termplot](#).

For smooth terms `plot.gam` actually calls plot method functions depending on the class of the smooth. Currently [random.effects](#), Markov random fields ([mrf](#)), [Spherical.Spline](#) and [factor.smooth.interaction](#) terms have special methods (documented in their help files), the rest use the defaults described below.

For plots of 1-d smooths, the x axis of each plot is labelled with the covariate name, while the y axis is labelled `s(cov, edf)` where `cov` is the covariate name, and `edf` the estimated (or user defined for regression splines) degrees of freedom of the smooth. `scheme == 0` produces a smooth curve with dashed curves indicating 2 standard error bounds. `scheme == 1` illustrates the error bounds using a shaded region.

For `scheme==0`, contour plots are produced for 2-d smooths with the x-axes labelled with the first covariate name and the y axis with the second covariate name. The main title of the plot is something like `s(var1, var2, edf)`, indicating the variables of which the term is a function, and the estimated degrees of freedom for the term. When `se=TRUE`, estimator variability is shown by overlaying contour plots at plus and minus 1 s.e. relative to the main estimate. If `se` is a positive number then contour plots are at plus or minus `se` multiplied by the s.e. Contour levels are chosen to try and ensure reasonable separation of the contours of the different plots, but this is not always easy to achieve. Note that these plots can not be modified to the same extent as the other plot.

For 2-d smooths `scheme==1` produces a perspective plot, while `scheme==2` produces a heatmap, with overlaid contours.

Smooths of more than 2 variables are not plotted, but see [vis.gam](#).

Fine control of plots for parametric terms can be obtained by calling [termplot](#) directly, taking care to use its `terms` argument.

Note that, if `seWithMean=TRUE`, the confidence bands include the uncertainty about the overall mean. In other words although each smooth is shown centred, the confidence bands are obtained as if every other term in the model was constrained to have average 0, (average taken over the covariate values), except for the smooth concerned. This seems to correspond more closely to how most users interpret componentwise intervals in practice, and also results in intervals with close to nominal (frequentist) coverage probabilities by an extension of Nychka's (1988) results presented in Marra and Wood (2012).

Several smooth plots methods using `image` will accept a `colors` argument, which can be anything documented in `heat.colors` (in which case something like `colors=rainbow(50)` is appropriate), or the `grey` function (in which case something like `colors=grey(0:50/50)` is needed). Another option is `contour.col` which will set the contour colour for some plots. These options are useful for producing grey scale pictures instead of colour.

Sometimes you may want a small change to a default plot, and the arguments to `plot.gam` just won't let you do it. In this case, the quickest option is sometimes to clone the `smooth.construct` and `Predict.matrix` methods for the smooth concerned, modifying only the returned smoother class (e.g. to `foo.smooth`). Then copy the plot method function for the original class (e.g. `mgcv:::plot.mgcv.smooth`), modify the source code to plot exactly as you want and rename the plot method function (e.g. `plot.foo.smooth`). You can then use the cloned smooth in models (e.g. `s(x, bs="foo")`), and it will automatically plot using the modified plotting function.

### Value

The functions main purpose is its side effect of generating plots. It also silently returns a list of the data used to produce the plots, which can be used to generate customized plots.

### WARNING

Note that the behaviour of this function is not identical to `plot.gam()` in S-PLUS.

Plotting can be slow for models fitted to large datasets. Set `rug=FALSE` to improve matters. If it's still too slow set `too.far=0`, but then take care not to overinterpret smooths away from supporting data.

Plots of 2-D smooths with standard error contours shown can not easily be customized.

The function can not deal with smooths of more than 2 variables!

### Author(s)

Simon N. Wood <simon.wood@r-project.org>

Henric Nilsson <henric.nilsson@statisticon.se> donated the code for the shade option.

The design is inspired by the S function of the same name described in Chambers and Hastie (1993) (but is not a clone).

---

polys.plot

*Plot geographic regions defined as polygons*

---

## Description

Produces plots of geographic regions defined by polygons, optionally filling the polygons with a color or grey shade dependent on a covariate.

## Usage

```
polys.plot(pc, z=NULL, scheme="heat", lab="", ...)
```

## Arguments

|        |   |
|--------|---|
| pc     | A named list of matrices. Each matrix has two columns. The matrix rows each define the vertex of a boundary polygon. If a boundary is defined by several polygons, then each of these must be separated by an NA row in the matrix. See <a href="#">mrf</a> for an example. |
| z      | A vector of values associated with each area (item) of pc. If the vector elements have names then these are used to match elements of z to areas defined in pc. Otherwise pc and z are assumed to be in the same order. If z is NULL then polygons are not filled.          |
| scheme | One of "heat" or "grey", indicating how to fill the polygons in accordance with the value of z.   |
| lab    | label for plot.   |
| ...    | other arguments to pass to plot (currently only if z is NULL).  |

## Details

Any polygon within another polygon counts as a hole in the area. Further nesting is dealt with by treating any point that is interior to an odd number of polygons as being within the area, and all other points as being exterior. The routine is provided to facilitate plotting with models containing [mrf](#) smooths.

## Value

Simply produces a plot.

## Author(s)

Simon Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

## See Also

[mrf](#) and [columb.polys](#).

## Examples

## see also ?mrf for use of z
require(mgcv)
data(columb.polys)
polys.plot(columb.polys)
```

---

predict.bam

*Prediction from fitted Big Additive Model model*

---

## Description

Essentially a wrapper for `predict.gam` for prediction from a model fitted by `bam`. Can compute on a parallel cluster.

Takes a fitted bam object produced by `bam` and produces predictions given a new set of values for the model covariates or the original values used for the model fit. Predictions can be accompanied by standard errors, based on the posterior distribution of the model coefficients. The routine can optionally return the matrix by which the model coefficients must be pre-multiplied in order to yield the values of the linear predictor at the supplied covariate values: this is useful for obtaining credible regions for quantities derived from the model (e.g. derivatives of smooths), and for lookup table prediction outside R (see example code below).

## Usage

```
## S3 method for class 'bam'
predict(object, newdata, type = "link", se.fit = FALSE, terms = NULL,
        exclude = NULL, block.size = 50000, newdata.guaranteed = FALSE,
        na.action = na.pass, cluster = NULL, discrete = TRUE, n.threads = 1, ...)
```

## Arguments

|         |   |
|---------|---|
| object  | a fitted bam object as produced by <code>bam</code> .   |
| newdata | A data frame or list containing the values of the model covariates at which predictions are required. If this is not provided then predictions corresponding to the original data are returned. If newdata is provided then it should contain all the variables needed for prediction: a warning is generated if not.   |
| type    | When this has the value "link" (default) the linear predictor (possibly with associated standard errors) is returned. When type="terms" each component of the linear predictor is returned separately (possibly with standard errors): this includes parametric model components, followed by each smooth component, but excludes any offset and any intercept. type="iterms" is the same, except that any standard errors returned for smooth components will include the uncertainty about the intercept/overall mean. When type="response" predictions on the scale of the response are returned (possibly with approximate standard errors). When type="lpmatrix" then a matrix is returned which yields the values of the linear predictor (minus any offset) when postmultiplied by the parameter vector (in this case se.fit is ignored). The latter option is most useful for getting variance estimates for quantities derived from the model: for example integrated quantities, or derivatives of smooths. A linear predictor matrix can also be used to implement approximate prediction outside R (see example code, below). |

|                                 |   |
|---------------------------------|---|
| <code>se.fit</code>             | when this is TRUE (not default) standard error estimates are returned for each prediction.  |
| <code>terms</code>              | if <code>type=="terms"</code> or <code>type="iterms"</code> then only results for the terms (smooth or parametric) named in this array will be returned. Otherwise any smooth terms not named in this array will be set to zero. If NULL then all terms are included.   |
| <code>exclude</code>            | if <code>type=="terms"</code> or <code>type="iterms"</code> then terms (smooth or parametric) named in this array will not be returned. Otherwise any smooth terms named in this array will be set to zero. If NULL then no terms are excluded.   |
| <code>block.size</code>         | maximum number of predictions to process per call to underlying code: larger is quicker, but more memory intensive.   |
| <code>newdata.guaranteed</code> | Set to TRUE to turn off all checking of newdata except for sanity of factor levels: this can speed things up for large prediction tasks, but newdata must be complete, with no NA values for predictors required in the model.  |
| <code>na.action</code>          | what to do about NA values in newdata. With the default <code>na.pass</code> , any row of newdata containing NA values for required predictors, gives rise to NA predictions (even if the term concerned has no NA predictors). <code>na.exclude</code> or <code>na.omit</code> result in the dropping of newdata rows, if they contain any NA values for required predictors. If newdata is missing then NA handling is determined from <code>object\$na.action</code> . |
| <code>cluster</code>            | <code>predict.bam</code> can compute in parallel using <a href="#">parLapply</a> from the <code>parallel</code> package, if it is supplied with a cluster on which to do this (a cluster here can be some cores of a single machine). See details and example code for <a href="#">bam</a> .  |
| <code>discrete</code>           | if TRUE then discrete prediction methods used with model fitted by discrete methods. FALSE for regular prediction.  |
| <code>n.threads</code>          | if <code>se.fit=TRUE</code> and discrete prediction is used then parallel computation can be used to speed up se calculation. This specifies number of hthreads to use.   |
| <code>...</code>                | other arguments.  |

## Details

The standard errors produced by `predict.gam` are based on the Bayesian posterior covariance matrix of the parameters  $V_p$  in the fitted `bam` object.

To facilitate plotting with [termplot](#), if object possesses an attribute `"para.only"` and `type=="terms"` then only parametric terms of order 1 are returned (i.e. those that `termplot` can handle).

Note that, in common with other prediction functions, any offset supplied to [gam](#) as an argument is always ignored when predicting, unlike offsets specified in the `gam` model formula.

See the examples in [predict.gam](#) for how to use the `lpmatrix` for obtaining credible regions for quantities derived from the model.

## Value

If `type=="lpmatrix"` then a matrix is returned which will give a vector of linear predictor values (minus any offset) at the supplied covariate values, when applied to the model coefficient vector. Otherwise, if `se.fit` is TRUE then a 2 item list is returned with items (both arrays) `fit` and `se.fit` containing predictions and associated standard error estimates, otherwise an array of predictions is returned. The dimensions of the returned arrays depends on whether `type` is `"terms"` or not: if it is then the array is 2 dimensional with each term in the linear predictor separate, otherwise the array

is 1 dimensional and contains the linear predictor/predicted values (or corresponding s.e.s). The linear predictor returned termwise will not include the offset or the intercept.

newdata can be a data frame, list or model.frame: if it's a model frame then all variables must be supplied.

## WARNING

Predictions are likely to be incorrect if data dependent transformations of the covariates are used within calls to smooths. See examples in [predict.gam](#).

## Author(s)

---

predict.gam

*Prediction from fitted GAM model*

---

## Description

Takes a fitted gam object produced by `gam()` and produces predictions given a new set of values for the model covariates or the original values used for the model fit. Predictions can be accompanied by standard errors, based on the posterior distribution of the model coefficients. The routine can optionally return the matrix by which the model coefficients must be pre-multiplied in order to yield the values of the linear predictor at the supplied covariate values: this is useful for obtaining credible regions for quantities derived from the model (e.g. derivatives of smooths), and for lookup table prediction outside R (see example code below).

**Usage**

```
## S3 method for class 'gam'
predict(object,newdata,type="link",se.fit=FALSE,terms=NULL,
        exclude=NULL,block.size=NULL,newdata.guaranteed=FALSE,
        na.action=na.pass,unconditional=FALSE,...)
```

**Arguments**

|                    |   |
|--------------------|---|
| object             | a fitted gam object as produced by gam().   |
| newdata            | A data frame or list containing the values of the model covariates at which predictions are required. If this is not provided then predictions corresponding to the original data are returned. If newdata is provided then it should contain all the variables needed for prediction: a warning is generated if not.   |
| type               | When this has the value "link" (default) the linear predictor (possibly with associated standard errors) is returned. When type="terms" each component of the linear predictor is returned separately (possibly with standard errors): this includes parametric model components, followed by each smooth component, but excludes any offset and any intercept. type="iterms" is the same, except that any standard errors returned for smooth components will include the uncertainty about the intercept/overall mean. When type="response" predictions on the scale of the response are returned (possibly with approximate standard errors). When type="lpmatrix" then a matrix is returned which yields the values of the linear predictor (minus any offset) when postmultiplied by the parameter vector (in this case se.fit is ignored). The latter option is most useful for getting variance estimates for quantities derived from the model: for example integrated quantities, or derivatives of smooths. A linear predictor matrix can also be used to implement approximate prediction outside R (see example code, below). |
| se.fit             | when this is TRUE (not default) standard error estimates are returned for each prediction.  |
| terms              | if type=="terms" or type="iterms" then only results for the terms (smooth or parametric) named in this array will be returned. Otherwise any smooth terms not named in this array will be set to zero. If NULL then all terms are included.   |
| exclude            | if type=="terms" or type="iterms" then terms (smooth or parametric) named in this array will not be returned. Otherwise any smooth terms named in this array will be set to zero. If NULL then no terms are excluded. Note that this is the term names as it appears in the model summary, see example.   |
| block.size         | maximum number of predictions to process per call to underlying code: larger is quicker, but more memory intensive. Set to < 1 to use total number of predictions as this. If NULL then block size is 1000 if new data supplied, and the number of rows in the model frame otherwise.   |
| newdata.guaranteed | Set to TRUE to turn off all checking of newdata except for sanity of factor levels: this can speed things up for large prediction tasks, but newdata must be complete, with no NA values for predictors required in the model.  |
| na.action          | what to do about NA values in newdata. With the default na.pass, any row of newdata containing NA values for required predictors, gives rise to NA predictions (even if the term concerned has no NA predictors). na.exclude or na.omit result in the dropping of newdata rows, if they contain any NA values for required predictors. If newdata is missing then NA handling is determined from object\$na.action.   |

unconditional if TRUE then the smoothing parameter uncertainty corrected covariance matrix is used, when available, otherwise the covariance matrix conditional on the estimated smoothing parameters is used.

... other arguments.

### Details

The standard errors produced by `predict.gam` are based on the Bayesian posterior covariance matrix of the parameters  $V_p$  in the fitted gam object.

To facilitate plotting with `termplot`, if object possesses an attribute "para.only" and `type=="terms"` then only parametric terms of order 1 are returned (i.e. those that `termplot` can handle).

Note that, in common with other prediction functions, any offset supplied to `gam` as an argument is always ignored when predicting, unlike offsets specified in the gam model formula.

See the examples for how to use the `lpmatrix` for obtaining credible regions for quantities derived from the model.

### Value

If `type=="lpmatrix"` then a matrix is returned which will give a vector of linear predictor values (minus any offset) at the supplied covariate values, when applied to the model coefficient vector. Otherwise, if `se.fit` is TRUE then a 2 item list is returned with items (both arrays) `fit` and `se.fit` containing predictions and associated standard error estimates, otherwise an array of predictions is returned. The dimensions of the returned arrays depends on whether `type` is "terms" or not: if it is then the array is 2 dimensional with each term in the linear predictor separate, otherwise the array is 1 dimensional and contains the linear predictor/predicted values (or corresponding s.e.s). The linear predictor returned termwise will not include the offset or the intercept.

`newdata` can be a data frame, list or model.frame: if it's a model frame then all variables must be supplied.

### WARNING

Predictions are likely to be incorrect if data dependent transformations of the covariates are used within calls to smooths. See examples.

Note that the behaviour of this function is not identical to `predict.gam()` in Splus.

`type=="terms"` does not exactly match what `predict.lm` does for parametric model components.

```

---

Predict.matrix

---

*Prediction methods for smooth terms in a GAM*

---

## Description

Takes smooth objects produced by `smooth.construct` methods and obtains the matrix mapping the parameters associated with such a smooth to the predicted values of the smooth at a set of new covariate values.

In practice this method is often called via the wrapper function [PredictMat](#).

## Usage

```
Predict.matrix(object,data)
Predict.matrix2(object,data)
```

## Arguments

|        |  |
|--------|--|
| object | is a smooth object produced by a <code>smooth.construct</code> method function. The object contains all the information required to specify the basis for a term of its class, and this information is used by the appropriate <code>Predict.matrix</code> function to produce a prediction matrix for new covariate values. Further details are given in <a href="#">smooth.construct</a> . |
| data   | A data frame containing the values of the (named) covariates at which the smooth term is to be evaluated. Exact requirements are as for <a href="#">smooth.construct</a> and <code>smooth.construct2</code> .  |

## Details

Smooth terms in a GAM formula are turned into smooth specification objects of class `xx.smooth.spec` during processing of the formula. Each of these objects is converted to a smooth object using an appropriate `smooth.construct` function. The `Predict.matrix` functions are used to obtain the matrix that will map the parameters associated with a smooth term to the predicted values for the term at new covariate values.

Note that new smooth classes can be added by writing a new `smooth.construct` method function and a corresponding `Predict.matrix` method function: see the example code provided for `smooth.construct` for details.

## Value

A matrix which will map the parameters associated with the smooth to the vector of values of the smooth evaluated at the covariate values given in `object`. If the smooth class is one which generates offsets the corresponding offset is returned as attribute `"offset"` of the matrix.

`Predict.matrix.cr.smooth`

*Predict matrix method functions*

---

## Description

The various built in smooth classes for use with [gam](#) have associate `Predict.matrix` method functions to enable prediction from the fitted model.

## Usage

```
## S3 method for class 'cr.smooth'  
Predict.matrix(object, data)  
## S3 method for class 'cs.smooth'  
Predict.matrix(object, data)  
## S3 method for class 'cyclic.smooth'  
Predict.matrix(object, data)  
## S3 method for class 'pspline.smooth'
```

```
Predict.matrix(object, data)
## S3 method for class 'tensor.smooth'
Predict.matrix(object, data)
## S3 method for class 'tprs.smooth'
Predict.matrix(object, data)
## S3 method for class 'ts.smooth'
Predict.matrix(object, data)
## S3 method for class 't2.smooth'
Predict.matrix(object, data)
```

### Arguments

|        |   |
|--------|---|
| object | a smooth object, usually generated by a <a href="#">smooth.construct</a> method having processed a smooth specification object generated by an <a href="#">s</a> or <a href="#">te</a> term in a <a href="#">gam</a> formula. |
| data   | A data frame containing the values of the (named) covariates at which the smooth term is to be evaluated. Exact requirements are as for <a href="#">smooth.construct</a> and <a href="#">smooth.construct2</a> .              |

### Details

The Predict matrix function is not normally called directly, but is rather used internally by [predict.gam](#) etc. to predict from a fitted [gam](#) model. See [Predict.matrix](#) for more details, or the specific [smooth.construct](#) pages for details on a particular smooth class.

### Value

A matrix mapping the coefficients for the smooth term to its values at the supplied data values.

### Author(s)

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

### References

```

---

Predict.matrix.soap.film

*Prediction matrix for soap film smooth*

---

### Description

Creates a prediction matrix for a soap film smooth object, mapping the coefficients of the smooth to the linear predictor component for the smooth. This is the [Predict.matrix](#) method function required by [gam](#).

## Usage

```
## S3 method for class 'soap.film'  
Predict.matrix(object,data)  
## S3 method for class 'sw'  
Predict.matrix(object,data)  
## S3 method for class 'sf'  
Predict.matrix(object,data)
```

## Arguments

|        |   |
|--------|---|
| object | A class "soap.film", "sf" or "sw" object.   |
| data   | A list list or data frame containing the arguments of the smooth at which predictions are required. |

## Details

The smooth object will be largely what is returned from [smooth.construct.so.smooth.spec](#), although elements X and S are not needed, and need not be present, of course.

## Value

A matrix. This may have an "offset" attribute corresponding to the contribution from any known boundary conditions on the smooth.

```

---

`print.gam`*Print a Generalized Additive Model object.*

---

## Description

The default print method for a `gam` object.

## Usage

```
## S3 method for class 'gam'  
print(x, ...)
```

## Arguments

`x, ...` fitted model objects of class `gam` as produced by `gam()`.

## Details

Prints out the family, model formula, effective degrees of freedom for each smooth term, and optimized value of the smoothness selection criterion used. See [gamObject](#) (or `names(x)`) for a listing of what the object contains. [summary.gam](#) provides more detail.

Note that the optimized smoothing parameter selection criterion reported is one of GCV, UBRE(AIC), GACV, negative log marginal likelihood (ML), or negative log restricted likelihood (REML).

If rank deficiency of the model was detected then the apparent rank is reported, along with the length of the coefficient vector (rank in absense of rank deficieny). Rank deficiency occurs when not all coefficients are identifiable given the data. Although the fitting routines (except `gamm`) deal gracefully with rank deficiency, interpretation of rank deficient models may be difficult.

qq.gam

*QQ plots for gam model residuals***Description**

Takes a fitted gam object produced by `gam()` and produces QQ plots of its residuals (conditional on the fitted model coefficients and scale parameter). If the model distributional assumptions are met then usually these plots should be close to a straight line (although discrete data can yield marked random departures from this line).

**Usage**

```
qq.gam(object, rep=0, level=.9, s.rep=10,
        type=c("deviance", "pearson", "response"),
        pch=".", rl.col=2, rep.col="gray80", ...)
```

**Arguments**

|                      |   |
|----------------------|---|
| <code>object</code>  | a fitted gam object as produced by <code>gam()</code> (or a <code>glm</code> object).   |
| <code>rep</code>     | How many replicate datasets to generate to simulate quantiles of the residual distribution. 0 results in an efficient simulation free method for direct calculation, if this is possible for the object family.             |
| <code>level</code>   | If simulation is used for the quantiles, then reference intervals can be provided for the QQ-plot, this specifies the level. 0 or less for no intervals, 1 or more to simply plot the QQ plot for each replicate generated. |
| <code>s.rep</code>   | how many times to randomize uniform quantiles to data under direct computation.   |
| <code>type</code>    | what sort of residuals should be plotted? See <a href="#">residuals.gam</a> .   |
| <code>pch</code>     | plot character to use. 19 is good.  |
| <code>rl.col</code>  | color for the reference line on the plot.   |
| <code>rep.col</code> | color for reference bands or replicate reference plots.   |
| <code>...</code>     | extra graphics parameters to pass to plotting functions.  |

**Details**

QQ-plots of the the model residuals can be produced in one of two ways. The cheapest method generates reference quantiles by associating a quantile of the uniform distribution with each datum, and feeding these uniform quantiles into the quantile function associated with each datum. The resulting quantiles are then used in place of each datum to generate approximate quantiles of residuals. The residual quantiles are averaged over `s.rep` randomizations of the uniform quantiles to data.

The second method is to use direct simulation. For each replicate, data are simulated from the fitted model, and the corresponding residuals computed. This is repeated `rep` times. Quantiles are readily obtained from the empirical distribution of residuals so obtained. From this method reference bands are also computable.

Even if `rep` is set to zero, the routine will attempt to simulate quantiles if no quantile function is available for the family. If no random deviate generating function family is available (e.g. for the

quasi families), then a normal QQ-plot is produced. The routine conditions on the fitted model coefficients and the scale parameter estimate.

The plots are very similar to those proposed in Ben and Yohai (2004), but are substantially cheaper to produce (the interpretation of residuals for binary data in Ben and Yohai is not recommended).

Note that plots for raw residuals from fits to binary data contain almost no useful information about model fit. Whether the residual is negative or positive is decided by whether the response is zero or one. The magnitude of the residual, given its sign, is determined entirely by the fitted values. In consequence only the most gross violations of the model are detectable from QQ-plots of residuals for binary data. To really check distributional assumptions from residuals for binary data you have to be able to group the data somehow. Binomial models other than binary are ok.

random.effects

*Random effects in GAMs*

---

## Description

The smooth components of GAMs can be viewed as random effects for estimation purposes. This means that more conventional random effects terms can be incorporated into GAMs in two ways. The first method converts all the smooths into fixed and random components suitable for estimation by standard mixed modelling software. Once the GAM is in this form then conventional random effects are easily added, and the whole model is estimated as a general mixed model. `gamm` and `gamm4` from the `gamm4` package operate in this way.

The second method represents the conventional random effects in a GAM in the same way that the smooths are represented — as penalized regression terms. This method can be used with `gam` by making use of `s(...,bs="re")` terms in a model: see [smooth.construct.re.smooth.spec](#), for full details. The basic idea is that, e.g., `s(x,z,g,bs="re")` generates an i.i.d. Gaussian random effect with model matrix given by `model.matrix(~x:z:g-1)` — in principle such terms can take any number of arguments. This simple approach is sufficient for implementing a wide range of commonly used random effect structures. For example if `g` is a factor then `s(g,bs="re")` produces a random coefficient for each level of `g`, with the random coefficients all modelled as i.i.d. normal. If `g` is a factor and `x` is numeric, then `s(x,g,bs="re")` produces an i.i.d. normal random slope relating the response to `x` for each level of `g`. If `h` is another factor then `s(h,g,bs="re")` produces

the usual i.i.d. normal  $g-h$  interaction. Note that a rather useful approximate test for zero random effect is also implemented for such terms based on Wood (2013). If the precision matrix is known to within a multiplicative constant, then this can be supplied via the `xt` argument of `s`. See [smooth.construct.re.smooth.spec](#) for details and example.

Alternatively, but less straightforwardly, the `paraPen` argument to `gam` can be used: see [gam.models](#). If smoothing parameter estimation is by ML or REML (e.g. `gam(...,method="REML")`) then this approach is a completely conventional likelihood based treatment of random effects.

`gam` can be slow for fitting models with large numbers of random effects, because it does not exploit the sparsity that is often a feature of parametric random effects. It can not be used for models with more coefficients than data. However `gam` is often faster and more reliable than `gamm` or `gamm4`, when the number of random effects is modest.

To facilitate the use of random effects with `gam`, [gam.vcomp](#) is a utility routine for converting smoothing parameters to variance components. It also provides confidence intervals, if smoothness estimation is by ML or REML.

Note that treating random effects as smooths does not remove the usual problems associated with testing variance components for equality to zero: see [summary.gam](#) and [anova.gam](#).

residuals.gam

*Generalized Additive Model residuals***Description**

Returns residuals for a fitted gam model object. Pearson, deviance, working and response residuals are available.

**Usage**

```
## S3 method for class 'gam'
residuals(object, type = "deviance",...)
```

**Arguments**

|        |   |
|--------|---|
| object | a gam fitted model object.  |
| type   | the type of residuals wanted. Usually one of "deviance", "pearson", "scaled.pearson", "working", or "response". |
| ...    | other arguments.  |

**Details**

Response residuals are the raw residuals (data minus fitted values). Scaled Pearson residuals are raw residuals divided by the standard deviation of the data according to the model mean variance relationship and estimated scale parameter. Pearson residuals are the same, but multiplied by the square root of the scale parameter (so they are independent of the scale parameter):  $((y - \mu) / \sqrt{V(\mu)})$ , where  $y$  is data  $\mu$  is model fitted value and  $V$  is model mean-variance relationship.). Both are provided since not all texts agree on the definition of Pearson residuals. Deviance residuals simply return the deviance residuals defined by the model family. Working residuals are the residuals returned from model fitting at convergence.

Families can supply their own residual function, which is used in place of the standard function if present, (e.g. [cox.ph](#)).

**Value**

A vector of residuals.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

rig

*Generate inverse Gaussian random deviates*

---

**Description**

Generates inverse Gaussian random deviates.

**Usage**

```
rig(n, mean, scale)
```

**Arguments**

|       |  |
|-------|--|
| n     | the number of deviates required. If this has length > 1 then the length is taken as the number of deviates required. |
| mean  | vector of mean values.   |
| scale | vector of scale parameter values (lambda, see below)   |

**Details**

If  $x$  is the returned vector, then  $E(x) = \text{mean}$  while  $\text{var}(x) = \text{scale} * \text{mean}^3$ . For density and distribution functions see the `statmod` package. The algorithm used is Algorithm 5.7 of Gentle (2003), based on Michael et al. (1976). Note that `scale` here is the scale parameter in the GLM sense, which is the reciprocal of the usual ‘lambda’ parameter.

**Value**

A vector of inverse Gaussian random deviates.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

## Examples

```
require(mgcv)
set.seed(7)
## An inverse.gaussian GAM example, by modify `gamSim` output...
dat <- gamSim(1,n=400,dist="normal",scale=1)
dat$f <- dat$f/4 ## true linear predictor
Ey <- exp(dat$f);scale <- .5 ## mean and GLM scale parameter
## simulate inverse Gaussian response...
dat$y <- rig(Ey,mean=Ey,scale=.2)
big <- gam(y~ s(x0)+ s(x1)+s(x2)+s(x3),family=inverse.gaussian(link=log),
  data=dat,method="REML")
plot(big,pages=1)
gam.check(big)
summary(big)
```

---

rmvn

*Generate multivariate normal deviates*

---

## Description

Generates multivariate normal random deviates.

## Usage

```
rmvn(n,mu,V)
```

## Arguments

|    |   |
|----|---|
| n  | number of simulated vectors required.   |
| mu | the mean of the vectors: either a single vector of length $p = \text{ncol}(V)$ or an $n$ by $p$ matrix. |
| V  | A positive semi definite covariance matrix.   |

## Details

Uses a ‘square root’ of  $V$  to transform stadard normal deviates to multivariate normal with the correct covariance matrix.

## Value

An  $n$  row matrix, with each row being a draw from a multivariate normal density with covariance matrix  $V$  and mean vector  $\mu$ . Alternatively each row may have a different mean vector if  $\mu$  is a vector.

## Author(s)

z <- rmvn(n,mu,V)
crossprod(sweep(z,2,colMeans(z)))/n ## observed covariance matrix
colMeans(z) ## observed mu
```

Rrank

*Find rank of upper triangular matrix***Description**

Finds rank of upper triangular matrix R, by estimating condition number of upper rank by rank block, and reducing rank until this is acceptably low. Assumes R has been computed by a method that uses pivoting, usually pivoted QR or Choleski.

**Usage**

```
Rrank(R,tol=.Machine$double.eps^.9)
```

**Arguments**

|     |   |
|-----|---|
| R   | An upper triangular matrix, obtained by pivoted QR or pivoted Choleski. |
| tol | the tolerance to use for judging rank.                                  |

**Details**

The method is based on Cline et al. (1979) as described in Golub and van Loan (1996).

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

**References**

**Examples**

```
set.seed(0)
n <- 10;p <- 5
X <- matrix(runif(n*(p-1)),n,p)
qrx <- qr(X,LAPACK=TRUE)
Rrank(qr.R(qrx))
```

---

rTweedie

*Generate Tweedie random deviates*

---

## Description

Generates Tweedie random deviates, for powers between 1 and 2.

## Usage

```
rTweedie(mu,p=1.5,phi=1)
```

## Arguments

|     |  |
|-----|--|
| mu  | vector of expected values for the deviates to be generated. One deviate generated for each element of mu.  |
| p   | the variance of a deviate is proportional to its mean, mu to the power p. p must be between 1 and 2. 1 is Poisson like (exactly Poisson if phi=1), 2 is gamma. |
| phi | The scale parameter. Variance of the deviates is given by $\phi \cdot \mu^p$ .   |

## Details

A Tweedie random variable with  $1 < p < 2$  is a sum of  $N$  gamma random variables where  $N$  has a Poisson distribution, with mean  $\mu^{(2-p)/((2-p)\phi)}$ . The Gamma random variables that are summed have shape parameter  $(2-p)/(p-1)$  and scale parameter  $\phi \cdot (p-1) \cdot \mu^{(p-1)}$  (note that this scale parameter is different from the scale parameter for a GLM with Gamma errors).

This is a restricted, but faster, version of `rtweedie` from the `tweedie` package.

## Value

A vector of random deviates from a Tweedie distribution, expected value vector mu, variance vector  $\phi \cdot \mu^p$ .

## Author(s)

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

f2 <- function(x) 0.2 * x^11 * (10 * (1 - x))^6 + 10 *
  (10 * x)^3 * (1 - x)^10
n <- 300
x <- runif(n)
mu <- exp(f2(x)/3+1.1); x <- x*10 - 4
y <- rTweedie(mu,p=1.5,phi=1.3)
b <- gam(y~s(x,k=20),family=Tweedie(p=1.5))
b
plot(b)
```

s

*Defining smooths in GAM formulae*

## Description

Function used in definition of smooth terms within gam model formulae. The function does not evaluate a (spline) smooth - it exists purely to help set up a model using spline based smooths.

## Usage

```
s(..., k=-1, fx=FALSE, bs="tp", m=NA, by=NA, xt=NULL, id=NULL, sp=NULL, pc=NULL)
```

## Arguments

- |     |   |
|-----|---|
| ... | a list of variables that are the covariates that this smooth is a function of. Transformations whose form depends on the values of the data are best avoided here: e.g. <code>s(log(x))</code> is fine, but <code>s(I(x/sd(x)))</code> is not (see <a href="#">predict.gam</a> ).   |
| k   | the dimension of the basis used to represent the smooth term. The default depends on the number of variables that the smooth is a function of. <code>k</code> should not be less than the dimension of the null space of the penalty for the term (see <a href="#">null.space.dimension</a> ), but will be reset if it is. See <a href="#">choose.k</a> for further information.  |
| fx  | indicates whether the term is a fixed d.f. regression spline (TRUE) or a penalized regression spline (FALSE).   |
| bs  | a two letter character string indicating the (penalized) smoothing basis to use. (eg "tp" for thin plate regression spline, "cr" for cubic regression spline). see <a href="#">smooth.terms</a> for an over view of what is available.  |
| m   | The order of the penalty for this term (e.g. 2 for normal cubic spline penalty with 2nd derivatives when using default t.p.s basis). NA signals autoinitialization. Only some smooth classes use this. The "ps" class can use a 2 item array giving the basis and penalty order separately.   |
| by  | a numeric or factor variable of the same dimension as each covariate. In the numeric vector case the elements multiply the smooth, evaluated at the corresponding covariate values (a 'varying coefficient model' results). For the numeric by variable case the resulting smooth is not usually subject to a centering constraint (so the <code>by</code> variable should not be added as an additional main effect). In the factor by variable case a replicate of the smooth is produced for |

each factor level (these smooths will be centered, so the factor usually needs to be added as a main effect as well). See [gam.models](#) for further details. A by variable may also be a matrix if covariates are matrices: in this case implements linear functional of a smooth (see [gam.models](#) and [linear.functional.terms](#) for details).

|    |  |
|----|--|
| xt | Any extra information required to set up a particular basis. Used e.g. to set large data set handling behaviour for "tp" basis.  |
| id | A label or integer identifying this term in order to link its smoothing parameters to others of the same type. If two or more terms have the same id then they will have the same smoothing parameters, and, by default, the same bases (first occurrence defines basis type, but data from all terms used in basis construction). An id with a factor by variable causes the smooths at each factor level to have the same smoothing parameter. |
| sp | any supplied smoothing parameters for this term. Must be an array of the same length as the number of penalties for this smooth. Positive or zero elements are taken as fixed smoothing parameters. Negative elements signal auto-initialization. Over-rides values supplied in sp argument to <a href="#">gam</a> . Ignored by <a href="#">gamm</a> .   |
| pc | If not NULL, signals a point constraint: the smooth should pass through zero at the point given here (as a vector or list with names corresponding to the smooth names). Never ignored if supplied. See <a href="#">identifiability</a> .  |

## Details

The function does not evaluate the variable arguments. To use this function to specify use of your own smooths, note the relationships between the inputs and the output object and see the example in [smooth.construct](#).

## Value

A class `xx.smooth.spec` object, where `xx` is a basis identifying code given by the `bs` argument of `s`. These `smooth.spec` objects define smooths and are turned into bases and penalties by `smooth.construct` method functions.

The returned object contains the following items:

|         |  |
|---------|--|
| term    | An array of text strings giving the names of the covariates that the term is a function of.  |
| bs.dim  | The dimension of the basis used to represent the smooth.   |
| fixed   | TRUE if the term is to be treated as a pure regression spline (with fixed degrees of freedom); FALSE if it is to be treated as a penalized regression spline |
| dim     | The dimension of the smoother - i.e. the number of covariates that it is a function of.  |
| p.order | The order of the t.p.r.s. penalty, or 0 for auto-selection of the penalty order.   |
| by      | is the name of any by variable as text ("NA" for none).  |
| label   | A suitable text label for this smooth term.  |
| xt      | The object passed in as argument <code>xt</code> .   |
| id      | An identifying label or number for the smooth, linking it to other smooths. Defaults to NULL for no linkage.   |
| sp      | array of smoothing parameters for the term (negative for auto-estimation). Defaults to NULL.   |

scat

---

*GAM scaled t family for heavy tailed data*

---

**Description**

Family for use with [gam](#), implementing regression for the heavy tailed response variables,  $y$ , using a scaled  $t$  model. The idea is that  $(y - \mu)/\sigma \sim t_\nu$  where  $\mu$  is determined by a linear predictor, while  $\sigma$  and  $\nu$  are parameters to be estimated alongside the smoothing parameters.

**Usage**

```
scat(theta = NULL, link = "identity")
```

**Arguments**

|       |   |
|-------|---|
| theta | the parameters to be estimated $\nu = 2 + \exp(\theta_1)$ and $\sigma = \exp(\theta_2)$ . If supplied and positive, then taken to be fixed values of $\nu$ and $\sigma$ . If any negative, then absolute values taken as starting values. |
| link  | The link function: one of "identity", "log" or "inverse".   |

**Details**

Useful in place of Gaussian, when data are heavy tailed.

**Value**

An object of class `extended.family`.

plot(b,pages=1)
```

---

sdiag

---

*Extract or modify diagonals of a matrix*

---

**Description**

Extracts or modifies sub- or super- diagonals of a matrix.

**Usage**

```
sdiag(A,k=0)
sdiag(A,k=0) <- value
```

**Arguments**

|       |   |
|-------|---|
| A     | a matrix  |
| k     | sub- (negative) or super- (positive) diagonal of a matrix. 0 is the leading diagonal. |
| value | single value, or vector of the same length as the diagonal.                           |

**Value**

A vector containing the requested diagonal, or a matrix with the requested diagonal replaced by value.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

**Examples**

```
require(mgcv)
A <- matrix(1:35,7,5)
A
sdiag(A,1) ## first super diagonal

```

---

single.index

*Single index models with mgcv*

---

**Description**

Single index models contain smooth terms with arguments that are linear combinations of other covariates. e.g.  $s(X\alpha)$  where  $\alpha$  has to be estimated. For identifiability, assume  $\|\alpha\| = 1$  with positive first element. One simple way to fit such models is to use [gam](#) to profile out the smooth model coefficients and smoothing parameters, leaving only the  $\alpha$  to be estimated by a general purpose optimizer.

Example code is provided below, which can be easily adapted to include multiple single index terms, parametric terms and further smooths. Note the initialization strategy. First estimate  $\alpha$  without penalization to get starting values and then do the full fit. Otherwise it is easy to get trapped in a local optimum in which the smooth is linear. An alternative is to initialize using fixed penalization (via the `sp` argument to [gam](#)).

**Author(s)**

**Examples**

```
require(mgcv)

si <- function(theta,y,x,z,opt=TRUE,k=10,fx=FALSE) {
  ## Fit single index model using gam call, given theta (defines alpha).
  ## Return ML if opt==TRUE and fitted gam with theta added otherwise.
  ## Suitable for calling from 'optim' to find optimal theta/alpha.
  alpha <- c(1,theta) ## constrained alpha defined using free theta
  kk <- sqrt(sum(alpha^2))
  alpha <- alpha/kk ## so now ||alpha||=1
  a <- x%*%alpha ## argument of smooth
```

```

b <- gam(y~s(a,fx=fx,k=k)+s(z),family=poisson,method="ML") ## fit model
if (opt) return(b$gcv.ubre) else {
  b$alpha <- alpha ## add alpha
  J <- outer(alpha,-theta/kk^2) ## compute Jacobian
  for (j in 1:length(theta)) J[j+1,j] <- J[j+1,j] + 1/kk
  b$J <- J ## dalpha_i/dtheta_j
  return(b)
}
} ## si

## simulate some data from a single index model...

set.seed(1)
f2 <- function(x) 0.2 * x^11 * (10 * (1 - x))^6 + 10 *
  (10 * x)^3 * (1 - x)^10
n <- 200;m <- 3
x <- matrix(runif(n*m),n,m) ## the covariates for the single index part
z <- runif(n) ## another covariate
alpha <- c(1,-1,.5); alpha <- alpha/sqrt(sum(alpha^2))
eta <- as.numeric(f2((x%*%alpha+.41)/1.4)+1+z^2*2)/4
mu <- exp(eta)
y <- rpois(n,mu) ## Poi response

## now fit to the simulated data...

th0 <- c(-.8,.4) ## close to truth for speed
## get initial theta, using no penalization...
f0 <- nlm(si,th0,y=y,x=x,z=z,fx=TRUE,k=5)
## now get theta/alpha with smoothing parameter selection...
f1 <- nlm(si,f0$estimate,y=y,x=x,z=z,hessian=TRUE,k=10)
theta.est <-f1$estimate

## Alternative using 'optim' ('Not run' simply to keep
## CRAN check time down)...
## Not run:
th0 <- rep(0,m-1)
## get initial theta, using no penalization...
f0 <- optim(th0,si,y=y,x=x,z=z,fx=TRUE,k=5)
## now get theta/alpha with smoothing parameter selection...
f1 <- optim(f0$par,si,y=y,x=x,z=z,hessian=TRUE,k=10)
theta.est <-f1$par

## End(Not run)
## extract and examine fitted model...

b <- si(theta.est,y,x,z,opt=FALSE) ## extract best fit model
plot(b,pages=1)

diag(Vt)^.5

```

slanczos

*Compute truncated eigen decomposition of a symmetric matrix***Description**

Uses Lanczos iteration to find the truncated eigen-decomposition of a symmetric matrix.

**Usage**

```
slanczos(A,k=10,k1=-1,tol=.Machine$double.eps^.5,nt=1)
```

**Arguments**

|     |   |
|-----|---|
| A   | A symmetric matrix.   |
| k   | Must be non-negative. If k1 is negative, then the k largest magnitude eigenvalues are found, together with the corresponding eigenvectors. If k1 is non-negative then the k highest eigenvalues are found together with their eigenvectors and the k1 lowest eigenvalues with eigenvectors are also returned. |
| k1  | If k1 is non-negative then the k1 lowest eigenvalues are returned together with their corresponding eigenvectors (in addition to the k highest eigenvalues + vectors). negative k1 signals that the k largest magnitude eigenvalues should be returned, with eigenvectors.                                    |
| tol | tolerance to use for convergence testing of eigenvalues. Error in eigenvalues will be less than the magnitude of the dominant eigenvalue multiplied by tol (or the machine precision!).   |
| nt  | number of threads to use for leading order iterative multiplication of A by vector. May show no speed improvement on two processor machine.   |

**Details**

If k1 is non-negative, returns the highest k and lowest k1 eigenvalues, with their corresponding eigenvectors. If k1 is negative, returns the largest magnitude k eigenvalues, with corresponding eigenvectors.

The routine implements Lanczos iteration with full re-orthogonalization as described in Demmel (1997). Lanczos iteration iteratively constructs a tridiagonal matrix, the eigenvalues of which converge to the eigenvalues of A, as the iteration proceeds (most extreme first). Eigenvectors can also be computed. For small k and k1 the approach is faster than computing the full symmetric eigendecomposition. The tridiagonal eigenproblems are handled using LAPACK.

The implementation is not optimal: in particular the inner tridiagonal problems could be handled more efficiently, and there would be some savings to be made by not always returning eigenvectors.

**Value**

A list with elements values (array of eigenvalues); vectors (matrix with eigenvectors in its columns); iter (number of iterations required).

**Author(s)**

## create some x's and knots...
set.seed(1);
n <- 700; A <- matrix(runif(n*n),n,n); A <- A+t(A)

## compare timings of slanczos and eigen
system.time(er <- slanczos(A,10))
system.time(um <- eigen(A,symmetric=TRUE))

## confirm values are the same...
ind <- c(1:6,(n-3):n)
range(er$values-um$values[ind]); range(abs(er$vectors)-abs(um$vectors[,ind]))
```

---

smooth.construct

*Constructor functions for smooth terms in a GAM*

---

## Description

Smooth terms in a GAM formula are turned into smooth specification objects of class `xx.smooth.spec` during processing of the formula. Each of these objects is converted to a smooth object using an appropriate `smooth.construct` function. New smooth classes can be added by writing a new `smooth.construct` method function and a corresponding `Predict.matrix` method function (see example code below).

In practice, `smooth.construct` is usually called via `smooth.construct2` and the wrapper function `smoothCon`, in order to handle by variables and centering constraints (see the `smoothCon` documentation if you need to handle these things directly, for a user defined smooth class).

## Usage

```
smooth.construct(object,data,knots)
smooth.construct2(object,data,knots)
```

## Arguments

**object** is a smooth specification object, generated by an `s` or `te` term in a GAM formula. Objects generated by `s` terms have class `xx.smooth.spec` where `xx` is given by the `bs` argument of `s` (this convention allows the user to add their own smoothers). If object is not class `tensor.smooth.spec` it will have the following elements:

**term** The names of the covariates for this smooth, in an array.

**bs.dim** Argument *k* of the *s* term generating the object. This is the dimension of the basis used to represent the term (or, arguably, 1 greater than the basis dimension for *cc* terms). *bs.dim*<0 indicates that the constructor should set this to the default value.

**fixed** TRUE if the term is to be unpenalized, otherwise FALSE.

**dim** the number covariates of which this smooth is a function.

**p.order** the order of the smoothness penalty or NA for autoselection of this. This is argument *m* of the *s* term that generated object.

**by** the name of any by variable to multiply this term as supplied as an argument to *s*. "NA" if there is no such term.

**label** A suitable label for use with this term.

**xt** An object containing information that may be needed for basis setup (used, e.g. by "tp" smooths to pass optional information on big dataset handling).

**id** Any identity associated with this term — used for linking bases and smoothing parameters. NULL by default, indicating no linkage.

**sp** Smoothing parameters for the term. Any negative are estimated, otherwise they are fixed at the supplied value. Unless NULL (default), over-rides *sp* argument to [gam](#).

If object is of class `tensor.smooth.spec` then it was generated by a *te* term in the GAM formula, and specifies a smooth of several variables with a basis generated as a tensor product of lower dimensional bases. In this case the object will be different and will have the following elements:

**margin** is a list of smooth specification objects of the type listed above, defining the bases which have their tensor product formed in order to construct this term.

**term** is the array of names of the covariates that are arguments of the smooth.

**by** is the name of any by variable, or "NA".

**fx** is an array, the elements of which indicate whether (TRUE) any of the margins in the tensor product should be unpenalized.

**label** A suitable label for use with this term.

**dim** is the number of covariates of which this smooth is a function.

**mp** TRUE if multiple penalties are to be used.

**np** TRUE if 1-D marginal smooths are to be re-parameterized in terms of function values.

**id** Any identity associated with this term — used for linking bases and smoothing parameters. NULL by default, indicating no linkage.

**sp** Smoothing parameters for the term. Any negative are estimated, otherwise they are fixed at the supplied value. Unless NULL (default), over-rides *sp* argument to [gam](#).

**data** For `smooth.construct` a data frame or list containing the evaluation of the elements of `object$term`, with names given by `object$term`. The last entry will be the by variable, if `object$by` is not "NA". For `smooth.construct2` data need only be an object within which `object$term` can be evaluated, the variables can be in any order, and there can be irrelevant variables present as well.

**knots** an optional data frame or list containing the knots relating to `object$term`. If it is NULL then the knot locations are generated automatically. The structure of knots should be as for `data`, depending on whether `smooth.construct` or `smooth.construct2` is used.

## Details

There are built in methods for objects with the following classes: `tp.smooth.spec` (thin plate regression splines: see [tprs](#)); `ts.smooth.spec` (thin plate regression splines with shrinkage-to-zero); `cr.smooth.spec` (cubic regression splines: see [cubic.regression.spline](#)); `cs.smooth.spec` (cubic regression splines with shrinkage-to-zero); `cc.smooth.spec` (cyclic cubic regression splines); `ps.smooth.spec` (Eilers and Marx (1986) style P-splines: see [p.spline](#)); `cp.smooth.spec` (cyclic P-splines); `ad.smooth.spec` (adaptive smooths of 1 or 2 variables: see [adaptive.smooth](#)); `re.smooth.spec` (simple random effect terms); `mrf.smooth.spec` (Markov random field smoothers for smoothing over discrete districts); `tensor.smooth.spec` (tensor product smooths).

There is an implicit assumption that the basis only depends on the knots and/or the set of unique covariate combinations; i.e. that the basis is the same whether generated from the full set of covariates, or just the unique combinations of covariates.

Plotting of smooths is handled by plot methods for smooth objects. A default `mgcv.smooth` method is used if there is no more specific method available. Plot methods can be added for specific smooth classes, see source code for `mgcv::plot.sos.smooth`, `mgcv::plot.random.effect`, `mgcv::plot.mgcv.smooth` for example code.

## Value

The input argument object, assigned a new class to indicate what type of smooth it is and with at least the following items added:

|                             |   |
|-----------------------------|---|
| <code>X</code>              | The model matrix from this term. This may have an "offset" attribute: a vector of length <code>nrow(X)</code> containing any contribution of the smooth to the model offset term. <code>by.variables</code> do not need to be dealt with here, but if they are then an item <code>by.done</code> must be added to the object. |
| <code>S</code>              | A list of positive semi-definite penalty matrices that apply to this term. The list will be empty if the term is to be left un-penalized.   |
| <code>rank</code>           | An array giving the ranks of the penalties.   |
| <code>null.space.dim</code> | The dimension of the penalty null space (before centering).   |

The following items may be added:

|                         |  |
|-------------------------|--|
| <code>C</code>          | The matrix defining any identifiability constraints on the term, for use when fitting. If this is <code>NULL</code> then <code>smoothCon</code> will add an identifiability constraint that each term should sum to zero over the covariate values. Set to a zero row matrix if no constraints are required. If a supplied <code>C</code> has an attribute "always.apply" then it is never ignored, even if any <code>by.variables</code> of a smooth imply that no constraint is actually needed. Code for creating <code>C</code> should check whether the specification object already contains a zero row matrix, and leave this unchanged if it is (since this signifies no constraint should be produced). |
| <code>Cp</code>         | An optional matrix supplying alternative identifiability constraints for use when predicting. By default the fitting constraints are used. This option is useful when some sort of simple sparse constraint is required for fitting, but the usual sum-to-zero constraint is required for prediction so that, e.g. the CIs for model components are as narrow as possible.   |
| <code>no.rescale</code> | if this is non- <code>NULL</code> then the penalty coefficient matrix of the smooth will not be rescaled for enhanced numerical stability (rescaling is the default, because <a href="#">gamm</a> requires it). Turning off rescaling is useful if the values of the smoothing parameters should be interpretable in a model, for example because they are inverse variance components.  |

|                |  |
|----------------|--|
| df             | the degrees of freedom associated with this term (when unpenalized and unconstrained). If this is null then smoothCon will set it to the basis dimension. smoothCon will reduce this by the number of constraints.   |
| te.ok          | 0 if this term should not be used as a tensor product marginal, 1 if it can be used and plotted, and 2 is it can be used but not plotted. Set to 1 if NULL.  |
| plot.me        | Set to FALSE if this smooth should not be plotted by <code>plot.gam</code> . Set to TRUE if NULL.  |
| side.constrain | Set to FALSE to ensure that the smooth is never subject to side constraints as a result of nesting.  |
| L              | smooths may depend on fewer 'underlying' smoothing parameters than there are elements of S. In this case L is the matrix mapping the vector of underlying log smoothing parameters to the vector of logs of the smoothing parameters actually multiplying the $S[[i]]$ . $L=NULL$ signifies that there is one smoothing parameter per $S[[i]]$ . |

Usually the returned object will also include extra information required to define the basis, and used by `Predict.matrix` methods to make predictions using the basis. See the Details section for links to the information included for the built in smooth classes.

`tensor.smooth` returned objects will additionally have each element of the margin list updated in the same way. `tensor.smooths` also have a list, `XP`, containing re-parameterization matrices for any 1-D marginal terms re-parameterized in terms of function values. This list will have NULL entries for marginal smooths that are not re-parameterized, and is only long enough to reach the last re-parameterized marginal in the list.

## WARNING

User defined smooth objects should avoid having attributes names "qrc" or "nCons" as these are used internally to provide constraint free parameterizations.

smooth.construct.ad.smooth.spec

*Adaptive smooths in GAMs*

---

## Description

`gam` can use adaptive smooths of one or two variables, specified via terms like `s(...,bs="ad",...)`. (`gamm` can not use such terms — check out package `AdaptFit` if this is a problem.) The basis for such a term is a (tensor product of) p-spline(s) or cubic regression spline(s). Discrete P-spline type penalties are applied directly to the coefficients of the basis, but the penalties themselves have a basis representation, allowing the strength of the penalty to vary with the covariates. The coefficients of the penalty basis are the smoothing parameters.

When invoking an adaptive smoother the `k` argument specifies the dimension of the smoothing basis (default 40 in 1D, 15 in 2D), while the `m` argument specifies the dimension of the penalty basis (default 5 in 1D, 3 in 2D). For an adaptive smooth of two variables `k` is taken as the dimension of both marginal bases: different marginal basis dimensions can be specified by making `k` a two element vector. Similarly, in the two dimensional case `m` is the dimension of both marginal bases for the penalties, unless it is a two element vector, which specifies different basis dimensions for each marginal (If the penalty basis is based on a thin plate spline then `m` specifies its dimension directly).

By default, P-splines are used for the smoothing and penalty bases, but this can be modified by supplying a list as argument `xt` with a character vector `xt$bs` specifying the smoothing basis type. Only "ps", "cp", "cc" and "cr" may be used for the smoothing basis. The penalty basis is always a B-spline, or a cyclic B-spline for cyclic bases.

The total number of smoothing parameters to be estimated for the term will be the dimension of the penalty basis. Bear in mind that adaptive smoothing places quite severe demands on the data. For example, setting `m=10` for a univariate smooth of 200 data is rather like estimating 10 smoothing parameters, each from a data series of length 20. The problem is particularly serious for smooths of 2 variables, where the number of smoothing parameters required to get reasonable flexibility in the penalty can grow rather fast, but it often requires a very large smoothing basis dimension to make good use of this flexibility. In short, adaptive smooths should be used sparingly and with care.

In practice it is often as effective to simply transform the smoothing covariate as it is to use an adaptive smooth.

**Usage**

```
## S3 method for class 'ad.smooth.spec'
smooth.construct(object, data, knots)
```

**Arguments**

|        |   |
|--------|---|
| object | a smooth specification object, usually generated by a term <code>s(...,bs="ad",...)</code>  |
| data   | a list containing just the data (including any by variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The by variable is the last element. |
| knots  | a list containing any knots supplied for basis setup — in same order and with same names as data. Can be NULL   |

**Details**

The constructor is not normally called directly, but is rather used internally by [gam](#). To use for basis setup it is recommended to use [smooth.construct2](#).

This class can not be used as a marginal basis in a tensor product smooth, nor by `gamm`.

**Value**

An object of class `"pspline.smooth"` in the 1D case or `"tensor.smooth"` in the 2D case.

smooth.construct.bs.smooth.spec

*Penalized B-splines in GAMs*

---

## Description

[gam](#) can use smoothing splines based on univariate B-spline bases with derivative based penalties, specified via terms like `s(x,bs="bs",m=c(3,2))`. `m[1]` controls the spline order, with `m[1]=3` being a cubic spline, `m[1]=2` being quadratic, and so on. The integrated square of the `m[2]`th derivative is used as the penalty. So `m=c(3,2)` is a conventional cubic spline. If `m` is supplied as a single number, then it is taken to be `m[1]` and `m[2]=m[1]-1`, which is only a conventional smoothing spline in the `m=3`, cubic spline case. Notice that the definition of the spline order in terms of `m[1]` is intuitive, but differs to that used with the [tprs](#) and [p.spline](#) bases. See details for options for controlling the interval over which the penalty is evaluated (which can matter if it is necessary to extrapolate).

## Usage

```
## S3 method for class 'bs.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'Bspline.smooth'
Predict.matrix(object, data)
```

## Arguments

|        |   |
|--------|---|
| object | a smooth specification object, usually generated by a term <code>s(x, bs="bs", ...)</code>  |
| data   | a list containing just the data (including any by variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The by variable is the last element. |
| knots  | a list containing any knots supplied for basis setup — in same order and with same names as data. Can be NULL. See details for further information.   |

## Details

The basis and penalty are sparse (although sparse matrices are not used to represent them). `m[2]>m[1]` will generate an error, since in that case the penalty would be based on an undefined derivative of the basis, which makes no sense.

The default basis dimension, `k`, is the larger of 10 and `m`. `m[1]` is the lower limit on basis dimension. If knots are supplied, then the number of supplied knots should be `k + m[1] + 1`, and the range of the middle `k-m[1]+1` knots should include all the covariate values. Alternatively, 2 knots can be supplied, denoting the lower and upper limits between which the spline can be evaluated (making this range too wide mean that there is no information about some basis coefficients, because the corresponding basis functions have a span that includes no data). Unlike P-splines, splines with derivative based penalties can have uneven knot spacing, without a problem.

Another option is to supply 4 knots. Then the outer 2 define the interval over which the penalty is to be evaluated, while the inner 2 define an interval within which all but the outermost 2 knots should lie. Normally the outer 2 knots would be the interval over which predictions might be required, while the inner 2 knots define the interval within which the data lie. This option allows the penalty to apply over a wider interval than the data, while still placing most of the basis functions where the data are. This is useful in situations in which it is necessary to extrapolate slightly with a smooth. Only applying the penalty over the interval containing the data amounts to a model in which the function could be less smooth outside the interval than within it, and leads to very wide extrapolation confidence intervals. However the alternative of evaluating the penalty over the whole real line amounts to asserting certainty that the function has some derivative zeroed away from the data, which is equally unreasonable. It is preferable to build a model in which the same smoothness assumptions apply over both data and extrapolation intervals, but not over the whole real line. See example code for practical illustration.

Linear extrapolation is used for prediction that requires extrapolation (i.e. prediction outside the range of the interior `k-m[1]+1` knots — the interval over which the penalty is evaluated). Such extrapolation is not allowed in basis construction, but is when predicting.

It is possible to set a `deriv` flag in a smooth specification or smooth object, so that a model or prediction matrix produces the requested derivative of the spline, rather than evaluating it.

## Value

An object of class "Bspline.smooth". See [smooth.construct](#), for the elements that this object will contain.

**WARNING**

`m` directly controls the spline order here, which is intuitively sensible, but different to other bases.

smooth.construct.cr.smooth.spec

*Penalized Cubic regression splines in GAMs*

---

## Description

`gam` can use univariate penalized cubic regression spline smooths, specified via terms like `s(x,bs="cr")`. `s(x,bs="cs")` specifies a penalized cubic regression spline which has had its penalty modified to shrink towards zero at high enough smoothing parameters (as the smoothing parameter goes to infinity a normal cubic spline tends to a straight line.) `s(x,bs="cc")` specifies a cyclic penalized cubic regression spline smooth.

‘Cardinal’ spline bases are used: Wood (2006) sections 4.1.2 and 4.1.3 gives full details. These bases have very low setup costs. For a given basis dimension, `k`, they typically perform a little less well than thin plate regression splines, but a little better than `p`-splines. See [te](#) to use these bases in tensor product smooths of several variables.

Default `k` is 10.

**Usage**

```
## S3 method for class 'cr.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'cs.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'cc.smooth.spec'
smooth.construct(object, data, knots)
```

**Arguments**

|        |   |
|--------|---|
| object | a smooth specification object, usually generated by a term <code>s(...,bs="cr",...)</code> , <code>s(...,bs="cs",...)</code> or <code>s(...,bs="cc",...)</code>   |
| data   | a list containing just the data (including any by variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The by variable is the last element. |
| knots  | a list containing any knots supplied for basis setup — in same order and with same names as data. Can be NULL. See details.   |

**Details**

The constructor is not normally called directly, but is rather used internally by [gam](#). To use for basis setup it is recommended to use [smooth.construct2](#).

If they are not supplied then the knots of the spline are placed evenly throughout the covariate values to which the term refers: For example, if fitting 101 data with an 11 knot spline of  $x$  then there would be a knot at every 10th (ordered)  $x$  value. The parameterization used represents the spline in terms of its values at the knots. The values at neighbouring knots are connected by sections of cubic polynomial constrained to be continuous up to and including second derivative at the knots. The resulting curve is a natural cubic spline through the values at the knots (given two extra conditions specifying that the second derivative of the curve should be zero at the two end knots).

The shrinkage version of the smooth, eigen-decomposes the wiggleness penalty matrix, and sets its 2 zero eigenvalues to small multiples of the smallest strictly positive eigenvalue. The penalty is then set to the matrix with eigenvectors corresponding to those of the original penalty, but eigenvalues set to the perturbed versions. This penalty matrix has full rank and shrinks the curve to zero at high enough smoothing parameters.

Note that the cyclic smoother will wrap at the smallest and largest covariate values, unless knots are supplied. If only two knots are supplied then they are taken as the end points of the smoother (provided all the data lie between them), and the remaining knots are generated automatically.

The cyclic smooth is not subject to the condition that second derivatives go to zero at the first and last knots.

**Value**

An object of class `"cr.smooth"` `"cs.smooth"` or `"cyclic.smooth"`. In addition to the usual elements of a smooth class documented under [smooth.construct](#), this object will contain:

|    |  |
|----|--|
| xp | giving the knot locations used to generate the basis.  |
| BD | class <code>"cyclic.smooth"</code> objects include matrix BD which transforms function values at the knots to second derivatives at the knots. |

smooth.construct.ds.smooth.spec

*Low rank Duchon 1977 splines*

---

## Description

Thin plate spline smoothers are a special case of the isotropic splines discussed in Duchon (1977). A subset of this more general class can be invoked by terms like `s(x, z, bs="ds", m=c(1, .5))` in a `gam` model formula. In the notation of Duchon (1977) `m` is given by `m[1]` (default value 2), while `s` is given by `m[2]` (default value 0).

Duchon's (1977) construction generalizes the usual thin plate spline penalty as follows. The usual TPS penalty is given by the integral of the squared Euclidian norm of a vector of mixed partial  $m$ th order derivatives of the function w.r.t. its arguments. Duchon re-expresses this penalty in the Fourier domain, and then weights the squared norm in the integral by the Euclidean norm of the Fourier frequencies, raised to the power  $2s$ . `s` is a user selected constant taking integer values divided by 2. If  $d$  is the number of arguments of the smooth, then it is required that  $-d/2 < s < d/2$ . To obtain continuous functions we further require that  $m + s > d/2$ . If  $s=0$  then the usual thin plate spline is recovered.

The construction is amenable to exactly the low rank approximation method given in Wood (2003) to thin plate splines, with similar optimality properties, so this approach to low rank smoothing is used here. For large datasets the same subsampling approach as is used in the `tprs` case is employed here to reduce computational costs.

These smoothers allow the use of lower orders of derivative in the penalty than conventional thin plate splines, while still yielding continuous functions. For example, we can set  $m = 1$  and  $s = d/2 -$

.5 in order to use first derivative penalization for any  $d$  (which has the advantage that the dimension of the null space of unpenalized functions is only  $d+1$ ).

### Usage

```
## S3 method for class 'ds.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'duchon.spline'
Predict.matrix(object, data)
```

### Arguments

|        |   |
|--------|---|
| object | a smooth specification object, usually generated by a term <code>s(...,bs="ds",...)</code> .  |
| data   | a list containing just the data (including any by variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The by variable is the last element. |
| knots  | a list containing any knots supplied for basis setup — in same order and with same names as data. Can be NULL   |

### Details

The default basis dimension for this class is  $k=M+k.def$  where  $M$  is the null space dimension (dimension of unpenalized function space) and  $k.def$  is 10 for dimension 1, 30 for dimension 2 and 100 for higher dimensions. This is essentially arbitrary, and should be checked, but as with all penalized regression smoothers, results are statistically insensitive to the exact choice, provided it is not so small that it forces oversmoothing (the smoother's degrees of freedom are controlled primarily by its smoothing parameter).

The constructor is not normally called directly, but is rather used internally by [gam](#). To use for basis setup it is recommended to use [smooth.construct2](#).

For these classes the specification object will contain information on how to handle large datasets in their `xt` field. The default is to randomly subsample 2000 'knots' from which to produce a reduced rank eigen approximation to the full basis, if the number of unique predictor variable combinations in excess of 2000. The default can be modified via the `xt` argument to [s](#). This is supplied as a list with elements `max.knots` and `seed` containing a number to use in place of 2000, and the random number seed to use (either can be missing). Note that the random sampling will not effect the state of R's RNG.

For these bases knots has two uses. Firstly, as mentioned already, for large datasets the calculation of the tp basis can be time-consuming. The user can retain most of the advantages of the approach by supplying a reduced set of covariate values from which to obtain the basis - typically the number of covariate values used will be substantially smaller than the number of data, and substantially larger than the basis dimension,  $k$ . This approach is the one taken automatically if the number of unique covariate values (combinations) exceeds `max.knots`. The second possibility is to avoid the eigen-decomposition used to find the spline basis altogether and simply use the basis implied by the chosen knots: this will happen if the number of knots supplied matches the basis dimension,  $k$ . For a given basis dimension the second option is faster, but gives poorer results (and the user must be quite careful in choosing knot locations).

### Value

An object of class "duchon.spline". In addition to the usual elements of a smooth class documented under [smooth.construct](#), this object will contain:

|                      |   |
|----------------------|---|
| shift                | A record of the shift applied to each covariate in order to center it around zero and avoid any co-linearity problems that might otehrwise occur in the penalty null space basis of the term. |
| Xu                   | A matrix of the unique covariate combinations for this smooth (the basis is constructed by first stripping out duplicate locations).  |
| UZ                   | The matrix mapping the smoother parameters back to the parameters of a full Duchon spline.  |
| null.space.dimension | The dimension of the space of functions that have zero wiggleness according to the wiggleness penalty for this term.  |

## Description

Simple factor smooth interactions, which are efficient when used with [gamm](#). This smooth class allows a separate smooth for each level of a factor, with the same smoothing parameter for all smooths. It is an alternative to using factor by variables.

See the discussion of by variables in [gam.models](#) for more general alternatives for factor smooth interactions (including interactions of tensor product smooths with factors).

## Usage

```
## S3 method for class 'fs.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'fs.interaction'
Predict.matrix(object, data)
```

## Arguments

|        |   |
|--------|---|
| object | For the <code>smooth.construct</code> method a smooth specification object, usually generated by a term <code>s(x, ..., bs="fs", )</code> . For the <code>Predict.Matrix</code> method an object of class <code>"fs.interaction"</code> produced by the <code>smooth.construct</code> method. |
| data   | a list containing just the data (including any by variable) required by this term, with names corresponding to <code>object\$term</code> .  |
| knots  | a list containing any knots supplied for smooth basis setup.  |

## Details

This class produces a smooth for each level of a single factor variable. Within a [gam](#) formula this is done with something like `s(x, fac, bs="fs")`, which is almost equivalent to `s(x, by=fac, id=1)` (with the `gam` argument `select=TRUE`). The terms are fully penalized, with separate penalties on each null space component: for this reason they are not centred (no sum-to-zero constraint).

The class is particularly useful for use with [gamm](#), where estimation efficiently exploits the nesting of the smooth within the factor. Note however that: i) `gamm` only allows one conditioning factor for smooths, so `s(x)+s(z, fac, bs="fs")+s(v, fac, bs="fs")` is OK, but `s(x)+s(z, fac1, bs="fs")+s(v, fac2, bs="fs")` is not; ii) all additional random effects and correlation structures will be treated as nested within the factor of the smooth factor interaction.

Note that `gamm4` from the `gamm4` package suffers from none of the restrictions that apply to `gamm`, and `"fs"` terms can be used without side-effects.

Any singly penalized basis can be used to smooth at each factor level. The default is `"tp"`, but alternatives can be supplied in the `xt` argument of `s` (e.g. `s(x, fac, bs="fs", xt="cr")` or `s(x, fac, bs="fs", xt=list(bs="cr"))`). The `k` argument to `s(..., bs="fs")` refers to the basis dimension to use for each level of the factor variable.

Note one computational bottleneck: currently [gamm](#) (or `gamm4`) will produce the full posterior covariance matrix for the smooths, including the smooths at each level of the factor. This matrix can get large and computationally costly if there are more than a few hundred levels of the factor. Even at one or two hundred levels, care should be taken to keep down `k`.

The plot method for this class has two schemes. `scheme==0` is in colour, while `scheme==1` is black and white.

## Value

An object of class `"fs.interaction"` or a matrix mapping the coefficients of the factor smooth interaction to the smooths themselves.

##       s(x2,k=20),method="ML")
## ... is exactly equivalent.
```

---

smooth.construct.gp.smooth.spec

*Low rank Gaussian process smooths*

---

**Description**

Gaussian process/kriging models based on simple covariance functions can be written in a very similar form to thin plate and Duchon spline models (e.g. Handcock, Meier, Nychka, 1994), and low rank versions produced by the eigen approximation method of Wood (2003). Kammann and Wand (2003) suggest a particularly simple form of the Matern covariance function with only a single smoothing parameter to estimate, and this class implements this and other similar models.

Usually invoked by an `s(...,bs="gp")` term in a `gam` formula. Argument `m` selects the covariance function, sets the range parameter and any power parameter. If `m` is not supplied then it defaults to NA and the covariance function suggested by Kammann and Wand (2003) along with their suggested

range parameter is used. Otherwise `m[1]` between 1 and 5 selects the correlation function from respectively, spherical, power exponential, and Matern with  $\kappa = 1.5, 2.5$  or  $3.5$ . `m[2]` if present specifies the range parameter, with non-positive or absent indicating that the Kammann and Wand estimate should be used. `m[3]` can be used to specify the power for the power exponential which otherwise defaults to 1.

## Usage

```
## S3 method for class 'gp.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'gp.smooth'
Predict.matrix(object, data)
```

## Arguments

|                     |   |
|---------------------|---|
| <code>object</code> | a smooth specification object, usually generated by a term <code>s(...,bs="ms",...)</code> .  |
| <code>data</code>   | a list containing just the data (including any by variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The by variable is the last element. |
| <code>knots</code>  | a list containing any knots supplied for basis setup — in same order and with same names as <code>data</code> . Can be NULL   |

## Details

Let  $\rho > 0$  be the range parameter,  $0 < \kappa \leq 2$  and  $d$  denote the distance between two points. Then the correlation functions indexed by `m[1]` are:

1.  $1 - 1.5d/\rho + 0.5(d/\rho)^3$  if  $d \leq \rho$  and 0 otherwise.
2.  $\exp(-(d/\rho)^\kappa)$ .
3.  $\exp(-d/\rho)(1 + d/\rho)$ .
4.  $\exp(-d/\rho)(1 + d/\rho + (d/\rho)^2/3)$ .
5.  $\exp(-d/\rho)(1 + d/\rho + 2(d/\rho)^2/5 + (d/\rho)^3/15)$ .

See Fahrmeir et al. (2013) section 8.1.6, for example.

The default basis dimension for this class is `k=M+k.def` where `M` is the null space dimension (dimension of unpenalized function space) and `k.def` is 10 for dimension 1, 30 for dimension 2 and 100 for higher dimensions. This is essentially arbitrary, and should be checked, but as with all penalized regression smoothers, results are statistically insensitive to the exact choice, provided it is not so small that it forces oversmoothing (the smoother's degrees of freedom are controlled primarily by its smoothing parameter).

The constructor is not normally called directly, but is rather used internally by [gam](#). To use for basis setup it is recommended to use [smooth.construct2](#).

For these classes the specification object will contain information on how to handle large datasets in their `xt` field. The default is to randomly subsample 2000 'knots' from which to produce a reduced rank eigen approximation to the full basis, if the number of unique predictor variable combinations in excess of 2000. The default can be modified via the `xt` argument to [s](#). This is supplied as a list with elements `max.knots` and `seed` containing a number to use in place of 2000, and the random number seed to use (either can be missing). Note that the random sampling will not effect the state of R's RNG.

For these bases knots has two uses. Firstly, as mentioned already, for large datasets the calculation of the tp basis can be time-consuming. The user can retain most of the advantages of the approach by supplying a reduced set of covariate values from which to obtain the basis - typically the number of covariate values used will be substantially smaller than the number of data, and substantially larger than the basis dimension,  $k$ . This approach is the one taken automatically if the number of unique covariate values (combinations) exceeds `max.knots`. The second possibility is to avoid the eigen-decomposition used to find the spline basis altogether and simply use the basis implied by the chosen knots: this will happen if the number of knots supplied matches the basis dimension,  $k$ . For a given basis dimension the second option is faster, but gives poorer results (and the user must be quite careful in choosing knot locations).

## Value

An object of class "gp.smooth". In addition to the usual elements of a smooth class documented under [smooth.construct](#), this object will contain:

|                                   |   |
|-----------------------------------|---|
| <code>shift</code>                | A record of the shift applied to each covariate in order to center it around zero and avoid any co-linearity problems that might otherwise occur in the penalty null space basis of the term. |
| <code>Xu</code>                   | A matrix of the unique covariate combinations for this smooth (the basis is constructed by first stripping out duplicate locations).  |
| <code>UZ</code>                   | The matrix mapping the smoother parameters back to the parameters of a full GP smooth.  |
| <code>null.space.dimension</code> | The dimension of the space of functions that have zero wiggleness according to the wiggleness penalty for this term.  |
| <code>gp.defn</code>              | the type, range parameter and power parameter defining the correlation function.  |

smooth.construct.mrf.smooth.spec

*Markov Random Field Smoother*

---

## Description

For data observed over discrete spatial units, a simple Markov random field smoother is sometimes appropriate. These functions provide such a smoother class for mgcv. See details for how to deal with regions with missing data.

## Usage

```

## S3 method for class 'mrf.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'mrf.smooth'
Predict.matrix(object, data)

```

## Arguments

|        |  |
|--------|--|
| object | For the smooth.construct method a smooth specification object, usually generated by a term <code>s(x, ..., bs="mrf", xt=list(polys=foo))</code> . <code>x</code> is a factor variable giving labels for geographic districts, and the <code>xt</code> argument is obligatory: see details. For the <code>Predict.matrix</code> method an object of class "mrf.smooth" produced by the smooth.construct method. |
| data   | a list containing just the data (including any by variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The by variable is the last element.  |
| knots  | If there are more geographic areas than data were observed for, then this argument is used to provide the labels for all the areas (observed and unobserved).  |

## Details

A Markov random field smooth over a set of discrete areas is defined using a set of area labels, and a neighbourhood structure for the areas. The covariate of the smooth is the vector of area labels corresponding to each observation. This covariate should be a factor, or capable of being coerced to a factor.

The neighbourhood structure is supplied in the `xt` argument to `s`. This must contain at least one of the elements `polys`, `nb` or `penalty`.

**polys** contains the polygons defining the geographic areas. It is a list with as many elements as there are geographic areas. `names(polys)` must correspond to the levels of the argument of the smooth, in any order (i.e. it gives the area labels). `polys[[i]]` is a 2 column matrix the

rows of which specify the vertices of the polygon(s) defining the boundary of the *i*th area. A boundary may be made up of several closed loops: these must be separated by NA rows. A polygon within another is treated as a hole. The first polygon in any `polys[[i]]` should not be a hole. An example of the structure is provided by `columb.polys` (which contains an artificial hole in its second element, for illustration). Any list elements with duplicate names are combined into a single NA separated matrix.

Plotting of the smooth is not possible without a `polys` object.

If `polys` is the only element of `xt` provided, then the neighbourhood structure is computed from it automatically. To count as neighbours, polygons must exactly share one or more vertices.

**nb** is a named list defining the neighbourhood structure. `names(nb)` must correspond to the levels of the covariate of the smooth (i.e. the area labels), but can be in any order. `nb[[i]]` is a vector indexing the neighbours of the *i*th area. All indices are relative to `nb` itself, but can be translated using `names(nb)`.

If no `penalty` is provided then it is computed automatically from this list. The *i*th row of the penalty matrix will be zero everywhere, except in the *i*th column, which will contain the number of neighbours of the *i*th geographic area, and the columns corresponding to those geographic neighbours, which will each contain -1.

**penalty** if this is supplied, then it is used as the penalty matrix. It should be positive semi-definite. Its row and column names should correspond to the levels of the covariate.

If no basis dimension is supplied then the constructor produces a full rank MRF, with a coefficient for each geographic area. Otherwise a low rank approximation is obtained based on truncation of the parameterization given in Wood (2006) Section 4.10.4.

Note that smooths of this class have a built in plot method, and that the utility function `in.out` can be useful for working with discrete area data. The plot method has two schemes, `scheme==0` is colour, `scheme==1` is grey scale.

The situation in which there are areas with no data requires special handling. You should set `drop.unused.levels=FALSE` in the model fitting function, `gam`, `bam` or `gamm`, having first ensured that any fixed effect factors do not contain unobserved levels. Also make sure that the basis dimension is set to ensure that the total number of coefficients is less than the number of observations.

## Value

An object of class `"mrf.smooth"` or a matrix mapping the coefficients of the MRF smooth to the predictions for the areas listed in `data`.

smooth.construct.ps.smooth.spec

*P-splines in GAMs*

---

## Description

**gam** can use univariate P-splines as proposed by Eilers and Marx (1996), specified via terms like `s(x,bs="ps")`. These terms use B-spline bases penalized by discrete penalties applied directly to the basis coefficients. Cyclic P-splines are specified by model terms like `s(x,bs="cp",...)`. These bases can be used in tensor product smooths (see [te](#)).

The advantage of P-splines is the flexible way that penalty and basis order can be mixed. This often provides a useful way of ‘taming’ an otherwise poorly behave smooth. However, in regular use, splines with derivative based penalties (e.g. `"tp"` or `"cr"` bases) tend to result in slightly better MSE performance, presumably because the good approximation theoretic properties of splines are rather closely connected to the use of derivative penalties.

## Usage

```
## S3 method for class 'ps.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'cp.smooth.spec'
smooth.construct(object, data, knots)
```

## Arguments

|        |   |
|--------|---|
| object | a smooth specification object, usually generated by a term <code>s(x,bs="ps",...)</code> or <code>s(x,bs="cp",...)</code> |
|--------|---|

|       |   |
|-------|---|
| data  | a list containing just the data (including any by variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The by variable is the last element. |
| knots | a list containing any knots supplied for basis setup — in same order and with same names as data. Can be NULL. See details for further information.   |

### Details

A smooth term of the form `s(x, bs="ps", m=c(2, 3))` specifies a 2nd order P-spline basis (cubic spline), with a third order difference penalty (0th order is a ridge penalty) on the coefficients. If `m` is a single number then it is taken as the basis order and penalty order. The default is the 'cubic spline like' `m=c(2, 2)`.

The default basis dimension, `k`, is the larger of 10 and `m[1]+1` for a "ps" terms and the larger of 10 and `m[1]` for a "cp" term. `m[1]+1` and `m[1]` are the lower limits on basis dimension for the two types.

If knots are supplied, then the number of knots should be one more than the basis dimension (i.e. `k+1`) for a "cp" smooth. For the "ps" basis the number of supplied knots should be `k + m[1] + 2`, and the range of the middle `k-m[1]` knots should include all the covariate values. See example.

Alternatively, for both types of smooth, 2 knots can be supplied, denoting the lower and upper limits between which the spline can be evaluated (Don't make this range too wide, however, or you can end up with no information about some basis coefficients, because the corresponding basis functions have a span that includes no data!). Note that P-splines don't make much sense with uneven knot spacing.

Linear extrapolation is used for prediction that requires extrapolation (i.e. prediction outside the range of the interior `k-m[1]` knots). Such extrapolation is not allowed in basis construction, but is when predicting.

For the "ps" basis it is possible to set flags in the smooth specification object, requesting setup according to the SCOP-spline monotonic smoother construction of Pya and Wood (2015). As yet this is not supported by any modelling functions in `mgcv` (see package `scam`). Similarly it is possible to set a `deriv` flag in a smooth specification or smooth object, so that a model or prediction matrix produces the requested derivative of the spline, rather than evaluating it. See examples below.

### Value

An object of class "pspline.smooth" or "cp.smooth". See [smooth.construct](#), for the elements that this object will contain.

```

---

smooth.construct.re.smooth.spec

*Simple random effects in GAMs*

---

## Description

`gam` can deal with simple independent random effects, by exploiting the link between smooths and random effects to treat random effects as smooths. `s(x,bs="re")` implements this. Such terms can have any number of predictors, which can be any mixture of numeric or factor variables. The terms produce a parametric interaction of the predictors, and penalize the corresponding coefficients with a multiple of the identity matrix, corresponding to an assumption of i.i.d. normality. See details.

## Usage

```

## S3 method for class 're.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'random.effect'
Predict.matrix(object, data)

```

## Arguments

|        |  |
|--------|--|
| object | For the <code>smooth.construct</code> method a smooth specification object, usually generated by a term <code>s(x,...,bs="re",)</code> . For the <code>predict.Matrix</code> method an object of class "random.effect" produced by the <code>smooth.construct</code> method. |
| data   | a list containing just the data (including any by variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The by variable is the last element.  |
| knots  | generically a list containing any knots supplied for basis setup — unused at present.  |

## Details

Exactly how the random effects are implemented is best seen by example. Consider the model term `s(x,z,bs="re")`. This will result in the model matrix component corresponding to `~x:z-1` being added to the model matrix for the whole model. The coefficients associated with the model matrix component are assumed i.i.d. normal, with unknown variance (to be estimated). This assumption

is equivalent to an identity penalty matrix (i.e. a ridge penalty) on the coefficients. Because such a penalty is full rank, random effects terms do not require centering constraints.

If the nature of the random effect specification is not clear, consider a couple more examples: `s(x,bs="re")` results in `model.matrix(~x-1)` being appended to the overall model matrix, while `s(x,v,w,bs="re")` would result in `model.matrix(~x:v:w-1)` being appended to the model matrix. In both cases the corresponding model coefficients are assumed i.i.d. normal, and are hence subject to ridge penalties.

If the random effect precision matrix is of the form  $\sum_j \lambda_j S_j$  for known matrices  $S_j$  and unknown parameters  $\lambda_j$ , then a list containing the  $S_j$  can be supplied in the `xt` argument of `s`. In this case an array `rank` should also be supplied in `xt` giving the ranks of the  $S_j$  matrices. See simple example below.

Note that `smooth ids` are not supported for random effect terms. Unlike most smooth terms, side conditions are never applied to random effect terms in the event of nesting (since they are identifiable without side conditions).

Random effects implemented in this way do not exploit the sparse structure of many random effects, and may therefore be relatively inefficient for models with large numbers of random effects, when `gamm4` or `gamm` may be better alternatives. Note also that `gam` will not support models with more coefficients than data.

The situation in which factor variable random effects intentionally have unobserved levels requires special handling. You should set `drop.unused.levels=FALSE` in the model fitting function, `gam`, `bam` or `gamm`, having first ensured that any fixed effect factors do not contain unobserved levels.

## Value

An object of class "random.effect" or a matrix mapping the coefficients of the random effect to the random effects themselves.

smooth.construct.so.smooth.spec

*Soap film smoother constructor*

---

## Description

Sets up basis functions and wiggleness penalties for soap film smoothers (Wood, Bravington and Hedley, 2008). Soap film smoothers are based on the idea of constructing a 2-D smooth as a film of soap connecting a smoothly varying closed boundary. Unless smoothing very heavily, the film is distorted towards the data. The smooths are designed not to smooth across boundary features (peninsulas, for example).

The so version sets up the full smooth. The sf version sets up just the boundary interpolating soap film, while the sw version sets up the wiggly component of a soap film (zero on the boundary). The latter two are useful for forming tensor products with soap films, and can be used with [gamm](#) and [gamm4](#). To use these to simply set up a basis, then call via the wrapper [smooth.construct2](#) or [smoothCon](#).

## Usage

```

## S3 method for class 'so.smooth.spec'
smooth.construct(object,data,knots)
## S3 method for class 'sf.smooth.spec'
smooth.construct(object,data,knots)
## S3 method for class 'sw.smooth.spec'
smooth.construct(object,data,knots)

```

## Arguments

|        |   |
|--------|---|
| object | A smooth specification object as produced by a <code>s(...,bs="so",xt=list(bnd=bnd,...))</code> term in a gam formula. Note that the <code>xt</code> argument to <code>s</code> <i>must</i> be supplied, and should be a list, containing at least a boundary specification list (see details). <code>xt</code> may also contain various options controlling the boundary smooth (see details), and PDE solution grid. The dimension of the bases for boundary loops is specified via the <code>k</code> argument of <code>s</code> , either as a single number to be used for each boundary loop, or as a vector of different basis dimensions for the various boundary loops. |
| data   | A list or data frame containing the arguments of the smooth.  |

**knots** list or data frame with two named columns specifying the knot locations within the boundary. The column names should match the names of the arguments of the smooth. The number of knots defines the *\*interior\** basis dimension (i.e. it is *\*not\** supplied via argument *k* of *s*).

## Details

For soap film smooths the following *\*must\** be supplied:

- *k* the basis dimension for each boundary loop smooth.
- *xt\$bnd* the boundary specification for the smooth.
- *knots* the locations of the interior knots for the smooth.

When used in a GAM then *k* and *xt* are supplied via *s* while *knots* are supplied in the *knots* argument of [gam](#).

The *bnd* element of the *xt* list is a list of lists (or data frames), specifying the loops that define the boundary. Each boundary loop list must contain 2 columns giving the co-ordinates of points defining a boundary loop (when joined sequentially by line segments). Loops should not intersect (not checked). A point is deemed to be in the region of interest if it is interior to an odd number of boundary loops. Each boundary loop list may also contain a column *f* giving known boundary conditions on a loop.

The *bndSpec* element of *xt*, if non-NULL, should contain

- *bs* the type of cyclic smoothing basis to use: one of "cc" and "cp". If not "cc" then a cyclic p-spline is used, and argument *m* must be supplied.
- *knot.space* set to "even" to get even knot spacing with the "cc" basis.
- *m* 1 or 2 element array specifying order of "cp" basis and penalty.

Currently the code will not deal with more than one level of nesting of loops, or with separate loops without an outer enclosing loop: if there are known boundary conditions (identifiability constraints get awkward).

Note that the function [locator](#) provides a simple means for defining boundaries graphically, using something like `bnd <- as.data.frame(locator(type="l"))`, after producing a plot of the domain of interest (right click to stop). If the real boundary is very complicated, it is probably better to use a simpler smooth boundary enclosing the true boundary, which represents the major boundary features that you don't want to smooth across, but doesn't follow every tiny detail.

Model set up, and prediction, involves evaluating basis functions which are defined as the solution to PDEs. The PDEs are solved numerically on a grid using sparse matrix methods, with bilinear interpolation used to obtain values at any location within the smoothing domain. The dimension of the PDE solution grid can be controlled via element *nmax* (default 200) of the list supplied as argument *xt* of *s* in a *gam* formula: it gives the number of cells to use on the longest grid side.

A little theory: the soap film smooth  $f(x, y)$  is defined as the solution of

$$f_{xx} + f_{yy} = g$$

subject to the condition that  $f = s$ , on the boundary curve, where  $s$  is a smooth function (usually a cyclic penalized regression spline). The function  $g$  is defined as the solution of

$$g_{xx} + g_{yy} = 0$$

where  $g = 0$  on the boundary curve and  $g(x_k, y_k) = c_k$  at the 'knots' of the surface; the  $c_k$  are model coefficients.

In the simplest case, estimation of the coefficients of  $f$  (boundary coefficients plus  $c_k$ 's) is by minimization of

$$\|z - f\|^2 + \lambda_s J_s(s) + \lambda_f J_f(f)$$

where  $J_s$  is usually some cubic spline type wiggleness penalty on the boundary smooth and  $J_f$  is the integral of  $(f_x x + f_y y)^2$  over the interior of the boundary. Both penalties can be expressed as quadratic forms in the model coefficients. The  $\lambda$ 's are smoothing parameters, selectable by GCV, REML, AIC, etc.  $z$  represents noisy observations of  $f$ .

### Value

A list with all the elements of object plus

|      |   |
|------|---|
| sd   | A list defining the PDE solution grid and domain boundary, and including the sparse LU factorization of the PDE coefficient matrix. |
| X    | The model matrix: this will have an "offset" attribute, if there are any known boundary conditions.                                 |
| S    | List of smoothing penalty matrices (in smallest non-zero submatrix form).   |
| irng | A vector of scaling factors that have been applied to the model matrix, to ensure nice conditioning.                                |

In addition there are all the elements usually added by `smooth.construct` methods.

### WARNINGS

Soap film smooths are quite specialized, and require more setup than most smoothers (e.g. you have to supply the boundary and the interior knots, plus the boundary smooth basis dimension(s)). It is worth looking at the reference.

smooth.construct.sos.smooth.spec

*Splines on the sphere*

---

## Description

`gam` can use isotropic smooths on the sphere, via terms like `s(la, lo, bs="sos", m=2, k=100)`. There must be exactly 2 arguments to such a smooth. The first is taken to be latitude (in degrees) and the second longitude (in degrees). `m` (default 0) is an integer in the range -1 to 4 determining the order of the penalty used. For  $m > 0$ ,  $(m+2)/2$  is the penalty order, with  $m=2$  equivalent to the usual second derivative penalty.  $m=0$  signals to use the 2nd order spline on the sphere, computed by Wendelberger's (1981) method.  $m = -1$  results in a [Duchon.spline](#) being used (with  $m=2$  and  $s=1/2$ ), following an unpublished suggestion of Jean Duchon.

`k` (default 50) is the basis dimension.

## Usage

```
## S3 method for class 'sos.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'sos.smooth'
Predict.matrix(object, data)
```

## Arguments

|                     |   |
|---------------------|---|
| <code>object</code> | a smooth specification object, usually generated by a term <code>s(..., bs="sos", ...)</code> .   |
| <code>data</code>   | a list containing just the data (including any by variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The by variable is the last element. |
| <code>knots</code>  | a list containing any knots supplied for basis setup — in same order and with same names as <code>data</code> . Can be NULL   |

## Details

For  $m > 0$ , the smooths implemented here are based on the pseudosplines on the sphere of Wahba (1981) (there is a correction of table 1 in 1982, but the correction has a misprint in the definition of  $A$  — the  $A$  given in the 1981 paper is correct). For  $m=0$  (default) then a second order spline on the sphere is used which is the analogue of a second order thin plate spline in 2D: the computation is based on Chapter 4 of Wendelberger, 1981. Optimal low rank approximations are obtained using exactly the approach given in Wood (2003). For  $m = -1$  a smooth of the general type discussed in Duchon (1977) is used: the sphere is embedded in a 3D Euclidean space, but smoothing employs a penalty based on second derivatives (so that locally as the smoothing parameter tends to zero we recover a "normal" thin plate spline on the tangent space). This is an unpublished suggestion of Jean Duchon.

Note that the null space of the penalty is always the space of constant functions on the sphere, whatever the order of penalty.

This class has a plot method, with 3 schemes. `scheme==0` plots one hemisphere of the sphere, projected onto a circle. The plotting sphere has the north pole at the top, and the 0 meridian running down the middle of the plot, and towards the viewer. The smoothing sphere is rotated within the

plotting sphere, by specifying the location of its pole in the co-ordinates of the viewing sphere. theta, phi give the longitude and latitude of the smoothing sphere pole within the plotting sphere (in plotting sphere co-ordinates). (You can visualize the smoothing sphere as a globe, free to rotate within the fixed transparent plotting sphere.) The value of the smooth is shown by a heat map overlaid with a contour plot. lat, lon gridlines are also plotted.

scheme==1 is as scheme==0, but in black and white, without the image plot. scheme>1 calls the default plotting method with scheme decremented by 2.

## Value

An object of class "sos.smooth". In addition to the usual elements of a smooth class documented under [smooth.construct](#), this object will contain:

|    |  |
|----|--|
| Xu | A matrix of the unique covariate combinations for this smooth (the basis is constructed by first stripping out duplicate locations). |
| UZ | The matrix mapping the parameters of the reduced rank spline back to the parameters of a full spline.                                |

*Tensor product smoothing constructor*

---

## Description

A special `smooth.construct` method function for creating tensor product smooths from any combination of single penalty marginal smooths, using the construction of Wood, Scheipl and Faraway (2013).

## Usage

```
## S3 method for class 't2.smooth.spec'
smooth.construct(object, data, knots)
```

## Arguments

|                     |   |
|---------------------|---|
| <code>object</code> | a smooth specification object of class <code>t2.smooth.spec</code> , usually generated by a term like <code>t2(x,z)</code> in a <a href="#">gam</a> model formula |
|---------------------|---|

|       |  |
|-------|--|
| data  | a list containing just the data (including any by variable) required by this term, with names corresponding to object\$term (and object\$by). The by variable is the last element. |
| knots | a list containing any knots supplied for basis setup — in same order and with same names as data. Can be NULL. See details for further information.                                |

### Details

Tensor product smooths are smooths of several variables which allow the degree of smoothing to be different with respect to different variables. They are useful as smooth interaction terms, as they are invariant to linear rescaling of the covariates, which means, for example, that they are insensitive to the measurement units of the different covariates. They are also useful whenever isotropic smoothing is inappropriate. See [t2](#), [te](#), [smooth.construct](#) and [smooth.terms](#). The construction employed here produces tensor smooths for which the smoothing penalties are non-overlapping portions of the identity matrix. This makes their estimation by mixed modelling software rather easy.

### Value

An object of class "t2.smooth".

`smooth.construct.tp.smooth.spec`

*Penalized thin plate regression splines in GAMs*

---

## Description

`gam` can use isotropic smooths of any number of variables, specified via terms like `s(x, z, bs="tp", m=3)` (or just `s(x, z)` as this is the default basis). These terms are based on thin plate regression splines. `m` specifies the order of the derivatives in the thin plate spline penalty. If `m` is a vector of length 2 and the second element is zero, then the penalty null space of the smooth is not included in the smooth: this is useful if you need to test whether a smooth could be replaced by a linear term, for example.

Thin plate regression splines are constructed by starting with the basis and penalty for a full thin plate spline and then truncating this basis in an optimal manner, to obtain a low rank smoother. Details are given in Wood (2003). One key advantage of the approach is that it avoids the knot placement problems of conventional regression spline modelling, but it also has the advantage that smooths of lower rank are nested within smooths of higher rank, so that it is legitimate to use conventional hypothesis testing methods to compare models based on pure regression splines. Note that the basis truncation does not change the meaning of the thin plate spline penalty (it penalizes exactly what it would have penalized for a full thin plate spline).

The t.p.r.s. basis and penalties can become expensive to calculate for large datasets. For this reason the default behaviour is to randomly subsample `max.knots` unique data locations if there are more than `max.knots` such, and to use the sub-sample for basis construction. The sampling is always done with the same random seed to ensure repeatability (does not reset R RNG). `max.knots` is 2000, by default. Both seed and `max.knots` can be modified using the `xt` argument to `s`. Alternatively the user can supply knots from which to construct a basis.

The "ts" smooths are t.p.r.s. with the penalty modified so that the term is shrunk to zero for high enough smoothing parameter, rather than being shrunk towards a function in the penalty null space (see details).

## Usage

```
## S3 method for class 'tp.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'ts.smooth.spec'
smooth.construct(object, data, knots)
```

## Arguments

|                     |   |
|---------------------|---|
| <code>object</code> | a smooth specification object, usually generated by a term <code>s(..., bs="tp", ...)</code> or <code>s(..., bs="ts", ...)</code>   |
| <code>data</code>   | a list containing just the data (including any by variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The by variable is the last element. |
| <code>knots</code>  | a list containing any knots supplied for basis setup — in same order and with same names as <code>data</code> . Can be NULL   |

## Details

The default basis dimension for this class is  $k = M + k_{\text{def}}$  where  $M$  is the null space dimension (dimension of unpenalized function space) and  $k_{\text{def}}$  is 8 for dimension 1, 27 for dimension 2 and 100 for higher dimensions. This is essentially arbitrary, and should be checked, but as with all penalized regression smoothers, results are statistically insensitive to the exact choice, provided it is not so small that it forces oversmoothing (the smoother's degrees of freedom are controlled primarily by its smoothing parameter).

The default is to set  $m$  (the order of derivative in the thin plate spline penalty) to the smallest value satisfying  $2m > d+1$  where  $d$  is the number of covariates of the term: this yields ‘visually smooth’ functions. In any case  $2m > d$  must be satisfied.

The constructor is not normally called directly, but is rather used internally by [gam](#). To use for basis setup it is recommended to use [smooth.construct2](#).

For these classes the specification object will contain information on how to handle large datasets in their `xt` field. The default is to randomly subsample 2000 ‘knots’ from which to produce a tprs basis, if the number of unique predictor variable combinations in excess of 2000. The default can be modified via the `xt` argument to [s](#). This is supplied as a list with elements `max.knots` and `seed` containing a number to use in place of 2000, and the random number seed to use (either can be missing).

For these bases `knots` has two uses. Firstly, as mentioned already, for large datasets the calculation of the `tp` basis can be time-consuming. The user can retain most of the advantages of the t.p.r.s. approach by supplying a reduced set of covariate values from which to obtain the basis - typically the number of covariate values used will be substantially smaller than the number of data, and substantially larger than the basis dimension,  $k$ . This approach is the one taken automatically if the number of unique covariate values (combinations) exceeds `max.knots`. The second possibility is to avoid the eigen-decomposition used to find the t.p.r.s. basis altogether and simply use the basis implied by the chosen knots: this will happen if the number of knots supplied matches the basis dimension,  $k$ . For a given basis dimension the second option is faster, but gives poorer results (and the user must be quite careful in choosing knot locations).

The shrinkage version of the smooth, eigen-decomposes the wiggleness penalty matrix, and sets its zero eigenvalues to small multiples of the smallest strictly positive eigenvalue. The penalty is then set to the matrix with eigenvectors corresponding to those of the original penalty, but eigenvalues set to the perturbed versions. This penalty matrix has full rank and shrinks the curve to zero at high enough smoothing parameters.

## Value

An object of class “`tprs.smooth`” or “`ts.smooth`”. In addition to the usual elements of a smooth class documented under [smooth.construct](#), this object will contain:

|                                   |   |
|-----------------------------------|---|
| <code>shift</code>                | A record of the shift applied to each covariate in order to center it around zero and avoid any co-linearity problems that might otherwise occur in the penalty null space basis of the term. |
| <code>Xu</code>                   | A matrix of the unique covariate combinations for this smooth (the basis is constructed by first stripping out duplicate locations).  |
| <code>UZ</code>                   | The matrix mapping the t.p.r.s. parameters back to the parameters of a full thin plate spline.  |
| <code>null.space.dimension</code> | The dimension of the space of functions that have zero wiggleness according to the wiggleness penalty for this term.  |

```

smooth.terms

*Smooth terms in GAM*

## Description

Smooth terms are specified in a `gam` formula using `s`, `te`, `ti` and `t2` terms. Various smooth classes are available, for different modelling tasks, and users can add smooth classes (see [user.defined.smooth](#)). What defines a smooth class is the basis used to represent the smooth function and quadratic penalty (or multiple penalties) used to penalize the basis coefficients in order to control the degree of smoothness. Smooth classes are invoked directly by `s` terms, or as building blocks for tensor product smoothing via `te`, `ti` or `t2` terms (only smooth classes with single penalties can be used in tensor products). The smooths built into the `mgcv` package are all based one way or another on low rank versions of splines. For the full rank versions see Wahba (1990).

Note that smooths can be used rather flexibly in `gam` models. In particular the linear predictor of the GAM can depend on (a discrete approximation to) any linear functional of a smooth term, using by variables and the ‘summation convention’ explained in [linear.functional.terms](#).

The single penalty built in smooth classes are summarized as follows

**Thin plate regression splines** `bs="tp"`. These are low rank isotropic smoothers of any number of covariates. By isotropic is meant that rotation of the covariate co-ordinate system will not change the result of smoothing. By low rank is meant that they have far fewer coefficients than there are data to smooth. They are reduced rank versions of the thin plate splines and use the thin plate spline penalty. They are the default smooth for `s` terms because there is a defined sense in which they are the optimal smoother of any given basis dimension/rank (Wood, 2003). Thin plate regression splines do not have ‘knots’ (at least not in any conventional sense): a truncated eigen-decomposition is used to achieve the rank reduction. See [tprs](#) for further details.

`bs="ts"` is as `"tp"` but with a modification to the smoothing penalty, so that the null space is also penalized slightly and the whole term can therefore be shrunk to zero.

**Duchon splines** `bs="ds"`. These generalize thin plate splines. In particular, for any given number of covariates they allow lower orders of derivative in the penalty than thin plate splines (and hence a smaller null space). See [Duchon.spline](#) for further details.

**Cubic regression splines** `bs="cr"`. These have a cubic spline basis defined by a modest sized set of knots spread evenly through the covariate values. They are penalized by the conventional integrated square second derivative cubic spline penalty. For details see [cubic.regression.spline](#) and e.g. Wood (2006a).

`bs="cs"` specifies a shrinkage version of `"cr"`.

`bs="cc"` specifies a cyclic cubic regression splines (see [cyclic.cubic.spline](#)). i.e. a penalized cubic regression splines whose ends match, up to second derivative.

**Splines on the sphere** `bs="sos"`. These are two dimensional splines on a sphere. Arguments are latitude and longitude, and they are the analogue of thin plate splines for the sphere. Useful for data sampled over a large portion of the globe, when isotropy is appropriate. See [Spherical.Spline](#) for details.

**P-splines** `bs="ps"`. These are P-splines as proposed by Eilers and Marx (1996). They combine a B-spline basis, with a discrete penalty on the basis coefficients, and any sane combination of penalty and basis order is allowed. Although this penalty has no exact interpretation in terms of function shape, in the way that the derivative penalties do, P-splines perform almost as well as conventional splines in many standard applications, and can perform better in particular cases where it is advantageous to mix different orders of basis and penalty.

`bs="cp"` gives a cyclic version of a P-spline (see [cyclic.p.spline](#)).

**Random effects** `bs="re"`. These are parametric terms penalized by a ridge penalty (i.e. the identity matrix). When such a smooth has multiple arguments then it represents the parametric interaction of these arguments, with the coefficients penalized by a ridge penalty. The ridge penalty is equivalent to an assumption that the coefficients are i.i.d. normal random effects. See [smooth.construct.re.smooth.spec](#).

**Markov Random Fields** `bs="mrf"`. These are popular when space is split up into discrete contiguous geographic units (districts of a town, for example). In this case a simple smoothing penalty is constructed based on the neighbourhood structure of the geographic units. See [mrf](#) for details and an example.

**Gaussian process smooths** `bs="gp"`. Gaussian process models with a variety of simple correlation functions can be represented as smooths. See [gp.smooth](#) for details.

**Soap film smooths** `bs="so"` (actually not single penalized, but `bs="sw"` and `bs="sf"` allows splitting into single penalty components for use in tensor product smoothing). These are finite area smoothers designed to smooth within complicated geographical boundaries, where the boundary matters (e.g. you do not want to smooth across boundary features). See [soap](#) for details.

Broadly speaking the default penalized thin plate regression splines tend to give the best MSE performance, but they are slower to set up than the other bases. The knot based penalized cubic regression splines (with derivative based penalties) usually come next in MSE performance, with the P-splines doing just a little worse. However the P-splines are useful in non-standard situations.

All the preceding classes (and any user defined smooths with single penalties) may be used as marginal bases for tensor product smooths specified via [te](#), [ti](#) or [t2](#) terms. Tensor product smooths are smooth functions of several variables where the basis is built up from tensor products of bases for smooths of fewer (usually one) variable(s) (marginal bases). The multiple penalties for these smooths are produced automatically from the penalties of the marginal smooths. Wood (2006b) and Wood, Scheipl and Faraway (2012), give the general recipe for these constructions.

- te** te smooths have one penalty per marginal basis, each of which is interpretable in a similar way to the marginal penalty from which it is derived. See Wood (2006b).
- ti** ti smooths exclude the basis functions associated with the ‘main effects’ of the marginal smooths, plus interactions other than the highest order specified. These provide a stable and interpretable way of specifying models with main effects and interactions. For example if we are interested in linear predictor  $f_1(x) + f_2(z) + f_3(x, z)$ , we might use model formula  $y \sim s(x) + s(z) + ti(x, z)$  or  $y \sim ti(x) + ti(z) + te(x, z)$ . A similar construction involving te terms instead will be much less statistically stable.
- t2** t2 uses an alternative tensor product construction that results in more penalties each having a simple non-overlapping structure allowing use with the gamm4 package. It is a natural generalization of the SS-ANOVA construction, but the penalties are a little harder to interpret. See Wood, Scheipl and Faraway (2012/13).

Tensor product smooths often perform better than isotropic smooths when the covariates of a smooth are not naturally on the same scale, so that their relative scaling is arbitrary. For example, if smoothing with respect to time and distance, an isotropic smoother will give very different results if the units are cm and minutes compared to if the units are metres and seconds: a tensor product smooth will give the same answer in both cases (see **te** for an example of this). Note that te terms are knot based, and the thin plate splines seem to offer no advantage over cubic or P-splines as marginal bases.

Some further specialist smoothers that are not suitable for use in tensor products are also available.

**Adaptive smoothers** `bs="ad"` Univariate and bivariate adaptive smooths are available (see [adaptive.smooth](#)). These are appropriate when the degree of smoothing should itself vary with the covariates to be smoothed, and the data contain sufficient information to be able to estimate the appropriate variation. Because this flexibility is achieved by splitting the penalty into several ‘basis penalties’ these terms are not suitable as components of tensor product smooths, and are not supported by gamm.

**Factor smooth interactions** `bs="fs"` Smooth factor interactions are often produced using by variables (see [gam.models](#)), but a special smoother class (see [factor.smooth.interaction](#)) is available for the case in which a smooth is required at each of a large number of factor levels (for example a smooth for each patient in a study), and each smooth should have the same smoothing parameter. The “fs” smoothers are set up to be efficient when used with [gamm](#), and have penalties on each null space component (i.e. they are fully ‘random effects’).

|               |  |
|---------------|--|
| smooth2random | <i>Convert a smooth to a form suitable for estimating as random effect</i> |
|---------------|--|

---

Description

A generic function for converting mgcv smooth objects to forms suitable for estimation as random effects by e.g. lme. Exported mostly for use by other package developers.

Usage

```
smooth2random(object,vnames,type=1)
```

Arguments

- object            an mgcv smooth object.
- vnames           a vector of names to avoid as dummy variable names in the random effects form.
- type             1 for lme, otherwise lmer.

Details

There is a duality between smooths and random effects which means that smooths can be estimated using mixed modelling software. This function converts standard mgcv smooth objects to forms suitable for estimation by lme, for example. A service routine for [gamm](#) exported for use by package developers.

Value

- A list.
- rand             a list of random effects, including grouping factors, and a fixed effects matrix. Grouping factors, model matrix and model matrix name attached as attributes, to each element.
- trans.D          A vector, trans.D, that transforms coefs, in order [rand1, rand2,... fix] back to original parameterization. If null, then taken as vector of ones. `b.original = trans.U %*% (trans.D*b.fit)`.
- trans.U          A matrix, trans.U, that transforms coefs, in order [rand1, rand2,... fix] back to original parameterization. If null, then not needed. If null then taken as identity.
- Xf               A matrix for the fixed effects, if any.

|         |  |
|---------|--|
| fixed   | TRUE/FALSE, indicating if term was unpenalized or not. If unpenalized then other stuff may not be returned (it's not a random effect). |
| rind    | an index vector such that if br is the vector of random coefficients for the term, br[rind] is the coefs in order for this term.       |
| pen.ind | index of which penalty penalizes each coefficient: 0 for unpenalized.  |

smooth2random(sm, "")
```

---

smoothCon

*Prediction/Construction wrapper functions for GAM smooth terms*

---

### Description

Wrapper functions for construction of and prediction from smooth terms in a GAM. The purpose of the wrappers is to allow user-transparent re-parameterization of smooth terms, in order to allow identifiability constraints to be absorbed into the parameterization of each term, if required. The routine also handles 'by' variables and construction of identifiability constraints automatically, although this behaviour can be over-ridden.

### Usage

```
smoothCon(object, data, knots=NULL, absorb.cons=FALSE,
          scale.penalty=TRUE, n=nrow(data), dataX=NULL,
          null.space.penalty=FALSE, sparse.cons=0,
          diagonal.penalty=FALSE, apply.by=TRUE, modCon=0)
PredictMat(object, data, n=nrow(data))
```

## Arguments

|                                 |   |
|---------------------------------|---|
| <code>object</code>             | is a smooth specification object or a smooth object.  |
| <code>data</code>               | A data frame, model frame or list containing the values of the (named) covariates at which the smooth term is to be evaluated. If it's a list then <code>n</code> must be supplied.   |
| <code>knots</code>              | An optional data frame supplying any knot locations to be supplied for basis construction.  |
| <code>absorb.cons</code>        | Set to TRUE in order to have identifiability constraints absorbed into the basis.   |
| <code>scale.penalty</code>      | should the penalty coefficient matrix be scaled to have approximately the same 'size' as the inner product of the terms model matrix with itself? This can improve the performance of <a href="#">gamm</a> fitting.   |
| <code>n</code>                  | number of values for each covariate, or if a covariate is a matrix, the number of rows in that matrix: must be supplied explicitly if <code>data</code> is a list.  |
| <code>dataX</code>              | Sometimes the basis should be set up using data in <code>data</code> , but the model matrix should be constructed with another set of data provided in <code>dataX</code> — <code>n</code> is assumed to be the same for both. Facilitates smooth id's.   |
| <code>null.space.penalty</code> | Should an extra penalty be added to the smooth which will penalize the components of the smooth in the penalty null space: provides a way of penalizing terms out of the model altogether.  |
| <code>apply.by</code>           | set to FALSE to have basis setup exactly as in default case, but to return add an additional matrix <code>X0</code> to the return object, containing the model matrix without the by variable, if a by variable is present. Useful for bam discrete method setup.   |
| <code>sparse.cons</code>        | If 0 then default sum to zero constraints are used. If -1 then sweep and drop sum to zero constraints are used (default with <a href="#">bam</a> ). If 1 then one coefficient is set to zero as constraint for sparse smooths. If 2 then sparse coefficient sum to zero constraints are used for sparse smooths. None of these options has an effect if the smooth supplies its own constraint. |
| <code>diagonal.penalty</code>   | If TRUE then the smooth is reparameterized to turn the penalty into an identity matrix, with the final diagonal elements zeroed (corresponding to the penalty nullspace). May result in a matrix <code>diagRP</code> in the returned object for use by <code>PredictMat</code> .  |
| <code>modCon</code>             | force modification of any smooth supplied constraints. 0 - do nothing. 1 - delete supplied constraints, replacing with automatically generated ones. 2 - set fit and predict constraint to predict constraint. 3 - set fit and predict constraint to fit constraint.  |

## Details

These wrapper functions exist to allow smooths specified using [smooth.construct](#) and [Predict.matrix](#) method functions to be re-parameterized so that identifiability constraints are no longer required in fitting. This is done in a user transparent manner, but is typically of no importance in use of GAMs. The routine's also handle by variables and will create default identifiability constraints.

If a user defined smooth constructor handles by variables itself, then its returned smooth object should contain an object `by.done`. If this does not exist then `smoothCon` will use the default code. Similarly if a user defined `Predict.matrix` method handles by variables internally then the returned matrix should have a `"by.done"` attribute.

Default centering constraints, that terms should sum to zero over the covariates, are produced unless the smooth constructor includes a matrix C of constraints. To have no constraints (in which case you had better have a full rank penalty!) the matrix C should have no rows. There is an option to use centering constraint that generate no, or limited infill, if the smoother has a sparse model matrix.

smoothCon returns a list of smooths because factor by variables result in multiple copies of a smooth, each multiplied by the dummy variable associated with one factor level. smoothCon modifies the smooth object labels in the presence of by variables, to ensure that they are unique, it also stores the level of a by variable factor associated with a smooth, for later use by PredictMat.

The parameterization used by `gam` can be controlled via `gam.control`.

## Value

From smoothCon a list of smooth objects returned by the appropriate `smooth.construct` method function. If constraints are to be absorbed then the objects will have attributes "qrc" and "nCons". "nCons" is the number of constraints. "qrc" is usually the qr decomposition of the constraint matrix (returned by `qr`), but if it is a single positive integer it is the index of the coefficient to set to zero, and if it is a negative number then this indicates that the parameters are to sum to zero.

For predictMat a matrix which will map the parameters associated with the smooth to the vector of values of the smooth evaluated at the covariate values given in object.

lines(times,Xp*%beta) ## overlay smooth
```

---

|         |  |
|---------|--|
| sp.vcov | <i>Extract smoothing parameter estimator covariance matrix from (RE)ML GAM fit</i> |
|---------|--|

---

## Description

Extracts the estimated covariance matrix for the log smoothing parameter estimates from a (RE)ML estimated gam object, provided the fit was with a method that evaluated the required Hessian.

## Usage

```
sp.vcov(x)
```

## Arguments

x                      a fitted model object of class gam as produced by gam().

## Details

Just extracts the inverse of the hessian matrix of the negative (restricted) log likelihood w.r.t the log smoothing parameters, if this has been obtained as part of fitting.

## Value

A matrix corresponding to the estimated covariance matrix of the log smoothing parameter estimators, if this can be extracted, otherwise NULL. If the scale parameter has been (RE)ML estimated (i.e. if the method was "ML" or "REML" and the scale parameter was unknown) then the last row and column relate to the log scale parameter.

step.gam

*Alternatives to step.gam***Description**

There is no `step.gam` in package `mgcv`. The `mgcv` default for model selection is to use either prediction error criteria such as GCV, GACV, Mallows' Cp/AIC/UBRE or the likelihood based methods of REML or ML. Since the smoothness estimation part of model selection is done in this way it is logically most consistent to perform the rest of model selection in the same way. i.e. to decide which terms to include or omit by looking at changes in GCV, AIC, REML etc.

To facilitate fully automatic model selection the package implements two smooth modification techniques which can be used to allow smooths to be shrunk to zero as part of smoothness selection.

**Shrinkage smoothers** are smoothers in which a small multiple of the identity matrix is added to the smoothing penalty, so that strong enough penalization will shrink all the coefficients of the smooth to zero. Such smoothers can effectively be penalized out of the model altogether, as part of smoothing parameter estimation. 2 classes of these shrinkage smoothers are implemented: "cs" and "ts", based on cubic regression spline and thin plate regression spline smoothers (see [s](#))

**Null space penalization** An alternative is to construct an extra penalty for each smooth which penalizes the space of functions of zero wiggleness according to its existing penalties. If all the smoothing parameters for such a term tend to infinity then the term is penalized to zero, and is effectively dropped from the model. The advantage of this approach is that it can be implemented automatically for any smooth. The `select` argument to `gam` causes this latter approach to be used. Unpenalized terms (e.g. `s(x, fx=TRUE)`) remain unpenalized.

REML and ML smoothness selection are equivalent under this approach, and simulation evidence suggests that they tend to perform a little better than prediction error criteria, for model selection.

summary.gam

*Summary for a GAM fit***Description**

Takes a fitted gam object produced by `gam()` and produces various useful summaries from it. (See [sink](#) to divert output to a file.)

**Usage**

```

## S3 method for class 'gam'
summary(object, dispersion=NULL, freq=FALSE, p.type = 0, ...)

## S3 method for class 'summary.gam'
print(x,digits = max(3, getOption("digits") - 3),
      signif.stars = getOption("show.signif.stars"),...)

```

**Arguments**

|                         |  |
|-------------------------|--|
| <code>object</code>     | a fitted gam object as produced by <code>gam()</code> .  |
| <code>x</code>          | a <code>summary.gam</code> object produced by <code>summary.gam()</code> .   |
| <code>dispersion</code> | A known dispersion parameter. NULL to use estimate or default (e.g. 1 for Poisson).  |
| <code>freq</code>       | By default p-values for parametric terms are calculated using the Bayesian estimated covariance matrix of the parameter estimators. If this is set to TRUE then the frequentist covariance matrix of the parameters is used instead. |

|                           |   |
|---------------------------|---|
| <code>p.type</code>       | determines how p-values are computed for smooth terms. 0 uses a test statistic with distribution determined by the un-rounded edf of the term. 1 uses upwardly biased rounding of the edf and -1 uses a version of the test statistic with a null distribution that has to be simulated. 5 is the approximation in Wood (2006). Other options are poor, generate a warning, and are only of research interest. See details. |
| <code>digits</code>       | controls number of digits printed in output.  |
| <code>signif.stars</code> | Should significance stars be printed alongside output.  |
| <code>...</code>          | other arguments.  |

## Details

Model degrees of freedom are taken as the trace of the influence (or hat) matrix  $\mathbf{A}$  for the model fit. Residual degrees of freedom are taken as number of data minus model degrees of freedom. Let  $\mathbf{P}_i$  be the matrix giving the parameters of the  $i$ th smooth when applied to the data (or pseudodata in the generalized case) and let  $\mathbf{X}$  be the design matrix of the model. Then  $\text{tr}(\mathbf{X}\mathbf{P}_i)$  is the edf for the  $i$ th term. Clearly this definition causes the edf's to add up properly! An alternative version of EDF is more appropriate for p-value computation, and is based on the trace of  $2\mathbf{A} - \mathbf{A}\mathbf{A}$ .

`print.summary.gam` tries to print various bits of summary information useful for term selection in a pretty way.

P-values for smooth terms are usually based on a test statistic motivated by an extension of Nychka's (1988) analysis of the frequentist properties of Bayesian confidence intervals for smooths (Marra and Wood, 2012). These have better frequentist performance (in terms of power and distribution under the null) than the alternative strictly frequentist approximation. When the Bayesian intervals have good coverage the function properties then the p-values have close to the correct null distribution and reasonable power (but there are no optimality results for the power). Full details are in Wood (2013b), although what is computed is actually a slight variant in which the components of the test statistic are weighted by the iterative fitting weights.

Note that for terms with no unpenalized terms (such as Gaussian random effects) the Nychka (1988) requirement for smoothing bias to be substantially less than variance breaks down (see e.g. appendix of Marra and Wood, 2012), and this results in incorrect null distribution for p-values computed using the above approach. In this case it is necessary to use an alternative approach designed for random effects variance components, and this is done. See Wood (2013a) for details: the test is based on a likelihood ratio statistic (with the reference distribution appropriate for the null hypothesis on the boundary of the parameter space).

All p-values are computed without considering uncertainty in the smoothing parameter estimates.

In simulations the p-values have best behaviour under ML smoothness selection, with REML coming second. In general the p-values behave well, but neglecting smoothing parameter uncertainty means that they may be somewhat too low when smoothing parameters are highly uncertain. High uncertainty happens in particular when smoothing parameters are poorly identified, which can occur with nested smooths or highly correlated covariates (high concavity).

If `p.type=5` then the frequentist approximation for p-values of smooth terms described in section 4.8.5 of Wood (2006) is used. The approximation is not as good as the default, and is no longer recommended.

By default the p-values for parametric model terms are also based on Wald tests using the Bayesian covariance matrix for the coefficients. This is appropriate when there are "re" terms present, and is otherwise rather similar to the results using the frequentist covariance matrix (`freq=TRUE`), since the parametric terms themselves are usually unpenalized. Default P-values for parameteric terms that are penalized using the `paraPen` argument will not be good. However if such terms represent conventional random effects with full rank penalties, then setting `freq=TRUE` is appropriate.

**Value**

summary.gam produces a list of summary information for a fitted gam object.

|               |  |
|---------------|--|
| p.coeff       | is an array of estimates of the strictly parametric model coefficients.  |
| p.t           | is an array of the p.coeff's divided by their standard errors.   |
| p.pv          | is an array of p-values for the null hypothesis that the corresponding parameter is zero. Calculated with reference to the t distribution with the estimated residual degrees of freedom for the model fit if the dispersion parameter has been estimated, and the standard normal if not.   |
| m             | The number of smooth terms in the model.   |
| chi.sq        | An array of test statistics for assessing the significance of model smooth terms. See details.   |
| s.pv          | An array of approximate p-values for the null hypotheses that each smooth term is zero. Be warned, these are only approximate.   |
| se            | array of standard error estimates for all parameter estimates.   |
| r.sq          | The adjusted r-squared for the model. Defined as the proportion of variance explained, where original variance and residual variance are both estimated using unbiased estimators. This quantity can be negative if your model is worse than a one parameter constant model, and can be higher for the smaller of two nested models! The proportion null deviance explained is probably more appropriate for non-normal errors. Note that r.sq does not include any offset in the one parameter model. |
| dev.expl      | The proportion of the null deviance explained by the model. The null deviance is computed taking account of any offset, so dev.expl can be substantially lower than r.sq when an offset is present.  |
| edf           | array of estimated degrees of freedom for the model terms.   |
| residual.df   | estimated residual degrees of freedom.   |
| n             | number of data.  |
| np            | number of model coefficients (regression coefficients, not smoothing parameters or other parameters of likelihood).  |
| rank          | apparent model rank.   |
| method        | The smoothing selection criterion used.  |
| sp.criterion  | The minimized value of the smoothness selection criterion. Note that for ML and REML methods, what is reported is the negative log marginal likelihood or negative log restricted likelihood.  |
| scale         | estimated (or given) scale parameter.  |
| family        | the family used.   |
| formula       | the original GAM formula.  |
| dispersion    | the scale parameter.   |
| pTerms.df     | the degrees of freedom associated with each parametric term (excluding the constant).  |
| pTerms.chi.sq | a Wald statistic for testing the null hypothesis that the each parametric term is zero.  |
| pTerms.pv     | p-values associated with the tests that each term is zero. For penalized fits these are approximate. The reference distribution is an appropriate chi-squared when the scale parameter is known, and is based on an F when it is not.  |

|              |   |
|--------------|---|
| cov.unscaled | The estimated covariance matrix of the parameters (or estimators if freq=TRUE), divided by scale parameter. |
| cov.scaled   | The estimated covariance matrix of the parameters (estimators if freq=TRUE).                                |
| p.table      | significance table for parameters   |
| s.table      | significance table for smooths  |
| p.Terms      | significance table for parametric model terms   |

## WARNING

The p-values are approximate and neglect smoothing parameter uncertainty. They are likely to be somewhat too low when smoothing parameter estimates are highly uncertain: do read the details section. If the exact values matter, read Wood (2013a or b).

P-values for terms penalized via ‘paraPen’ are unlikely to be correct.

t2

*Define alternative tensor product smooths in GAM formulae*

## Description

Alternative to [te](#) for defining tensor product smooths in a [gam](#) formula. Results in a construction in which the penalties are non-overlapping multiples of identity matrices (with some rows and columns zeroed). The construction, which is due to Fabian Scheipl (mgcv implementation, 2010), is analogous to Smoothing Spline ANOVA (Gu, 2002), but using low rank penalized regression spline marginals. The main advantage of this construction is that it is useable with `gamm4` from package `gamm4`.

## Usage

```
t2(..., k=NA,bs="cr",m=NA,d=NA,by=NA,xt=NULL,
  id=NULL,sp=NULL,full=FALSE,ord=NULL,pc=NULL)
```

## Arguments

... a list of variables that are the covariates that this smooth is a function of. Transformations whose form depends on the values of the data are best avoided here: e.g. `t2(log(x), z)` is fine, but `t2(I(x/sd(x)), z)` is not (see [predict.gam](#)).

|      |   |
|------|---|
| k    | the dimension(s) of the bases used to represent the smooth term. If not supplied then set to $5^d$ . If supplied as a single number then this basis dimension is used for each basis. If supplied as an array then the elements are the dimensions of the component (marginal) bases of the tensor product. See <a href="#">choose.k</a> for further information.   |
| bs   | array (or single character string) specifying the type for each marginal basis. "cr" for cubic regression spline; "cs" for cubic regression spline with shrinkage; "cc" for periodic/cyclic cubic regression spline; "tp" for thin plate regression spline; "ts" for t.p.r.s. with extra shrinkage. See <a href="#">smooth.terms</a> for details and full list. User defined bases can also be used here (see <a href="#">smooth.construct</a> for an example). If only one basis code is given then this is used for all bases.  |
| m    | The order of the spline and its penalty (for smooth classes that use this) for each term. If a single number is given then it is used for all terms. A vector can be used to supply a different m for each margin. For marginals that take vector m (e.g. <a href="#">p.spline</a> and <a href="#">Duchon.spline</a> ), then a list can be supplied, with a vector element for each margin. NA autoinitializes. m is ignored by some bases (e.g. "cr").   |
| d    | array of marginal basis dimensions. For example if you want a smooth for 3 covariates made up of a tensor product of a 2 dimensional t.p.r.s. basis and a 1-dimensional basis, then set $d=c(2,1)$ . Incompatibilities between built in basis types and dimension will be resolved by resetting the basis type.   |
| by   | a numeric or factor variable of the same dimension as each covariate. In the numeric vector case the elements multiply the smooth evaluated at the corresponding covariate values (a 'varying coefficient model' results). In the factor case causes a replicate of the smooth to be produced for each factor level. See <a href="#">gam.models</a> for further details. May also be a matrix if covariates are matrices: in this case implements linear functional of a smooth (see <a href="#">gam.models</a> and <a href="#">linear.functional.terms</a> for details). |
| xt   | Either a single object, providing any extra information to be passed to each marginal basis constructor, or a list of such objects, one for each marginal basis.  |
| id   | A label or integer identifying this term in order to link its smoothing parameters to others of the same type. If two or more smooth terms have the same id then they will have the same smoothing parameters, and, by default, the same bases (first occurrence defines basis type, but data from all terms used in basis construction).   |
| sp   | any supplied smoothing parameters for this term. Must be an array of the same length as the number of penalties for this smooth. Positive or zero elements are taken as fixed smoothing parameters. Negative elements signal auto-initialization. Over-rides values supplied in sp argument to <a href="#">gam</a> . Ignored by <a href="#">gamm</a> .  |
| full | If TRUE then there is a separate penalty for each combination of null space column and range space. This gives strict invariance. If FALSE each combination of null space and range space generates one penalty, but the columns of each null space basis are treated as one group. The latter is more parsimonious, but does mean that invariance is only achieved by an arbitrary rescaling of null space basis vectors.  |
| ord  | an array giving the orders of terms to retain. Here order means number of marginal range spaces used in the construction of the component. NULL to retain everything.   |

pc If not NULL, signals a point constraint: the smooth should pass through zero at the point given here (as a vector or list with names corresponding to the smooth names). Never ignored if supplied. See [identifiability](#).

## Details

Smooths of several covariates can be constructed from tensor products of the bases used to represent smooths of one (or sometimes more) of the covariates. To do this ‘marginal’ bases are produced with associated model matrices and penalty matrices. These are reparameterized so that the penalty is zero everywhere, except for some elements on the leading diagonal, which all have the same non-zero value. This reparameterization results in an unpenalized and a penalized subset of parameters, for each marginal basis (see e.g. appendix of Wood, 2004, for details).

The re-parameterized marginal bases are then combined to produce a basis for a single function of all the covariates (dimension given by the product of the dimensions of the marginal bases). In this set up there are multiple penalty matrices — all zero, but for a mixture of a constant and zeros on the leading diagonal. No two penalties have a non-zero entry in the same place.

Essentially the basis for the tensor product can be thought of as being constructed from a set of products of the penalized (range) or unpenalized (null) space bases of the marginal smooths (see Gu, 2002, section 2.4). To construct one of the set, choose either the null space or the range space from each marginal, and from these bases construct a product basis. The result is subject to a ridge penalty (unless it happens to be a product entirely of marginal null spaces). The whole basis for the smooth is constructed from all the different product bases that can be constructed in this way. The separately penalized components of the smooth basis each have an interpretation in terms of the ANOVA - decomposition of the term. See [pen.edf](#) for some further information.

Note that there are two ways to construct the product. When `full=FALSE` then the null space bases are treated as a whole in each product, but when `full=TRUE` each null space column is treated as a separate null space. The latter results in more penalties, but is the strict analog of the SS-ANOVA approach.

Tensor product smooths are especially useful for representing functions of covariates measured in different units, although they are typically not quite as nicely behaved as t.p.r.s. smooths for well scaled covariates.

Note also that GAMs constructed from lower rank tensor product smooths are nested within GAMs constructed from higher rank tensor product smooths if the same marginal bases are used in both cases (the marginal smooths themselves are just special cases of tensor product smooths.)

Note that tensor product smooths should not be centred (have identifiability constraints imposed) if any marginals would not need centering. The constructor for tensor product smooths ensures that this happens.

The function does not evaluate the variable arguments.

## Value

A class `t2.smooth.spec` object defining a tensor product smooth to be turned into a basis and penalties by the `smooth.construct.tensor.smooth.spec` function.

The returned object contains the following items:

|        |  |
|--------|--|
| margin | A list of <code>smooth.spec</code> objects of the type returned by <a href="#">s</a> , defining the basis from which the tensor product smooth is constructed. |
| term   | An array of text strings giving the names of the covariates that the term is a function of.  |
| by     | is the name of any by variable as text ("NA" for none).  |

|       |   |
|-------|---|
| fx    | logical array with element for each penalty of the term (tensor product smooths have multiple penalties). TRUE if the penalty is to be ignored, FALSE, otherwise. |
| label | A suitable text label for this smooth term.   |
| dim   | The dimension of the smoother - i.e. the number of covariates that it is a function of.   |
| mp    | TRUE is multiple penalties are to be used (default).  |
| np    | TRUE to re-parameterize 1-D marginal smooths in terms of function values (default).   |
| id    | the id argument supplied to te.   |
| sp    | the sp argument supplied to te.   |

te

*Define tensor product smooths or tensor product interactions in GAM formulae*

## Description

Functions used for the definition of tensor product smooths and interactions within gam model formulae. `te` produces a full tensor product smooth, while `ti` produces a tensor product interaction, appropriate when the main effects (and any lower interactions) are also present.

The functions do not evaluate the smooth - they exist purely to help set up a model using tensor product based smooths. Designed to construct tensor products from any marginal smooths with a basis-penalty representation (with the restriction that each marginal smooth must have only one penalty).

## Usage

```
te(..., k=NA, bs="cr", m=NA, d=NA, by=NA, fx=FALSE,
    mp=TRUE, np=TRUE, xt=NULL, id=NULL, sp=NULL, pc=NULL)
ti(..., k=NA, bs="cr", m=NA, d=NA, by=NA, fx=FALSE,
    np=TRUE, xt=NULL, id=NULL, sp=NULL, mc=NULL, pc=NULL)
```

## Arguments

- `...` a list of variables that are the covariates that this smooth is a function of. Transformations whose form depends on the values of the data are best avoided here: e.g. `te(log(x), z)` is fine, but `te(I(x/sd(x)), z)` is not (see [predict.gam](#)).
- `k` the dimension(s) of the bases used to represent the smooth term. If not supplied then set to  $5^d$ . If supplied as a single number then this basis dimension is used for each basis. If supplied as an array then the elements are the dimensions of the component (marginal) bases of the tensor product. See [choose.k](#) for further information.
- `bs` array (or single character string) specifying the type for each marginal basis. "cr" for cubic regression spline; "cs" for cubic regression spline with shrinkage; "cc" for periodic/cyclic cubic regression spline; "tp" for thin plate regression spline; "ts" for t.p.r.s. with extra shrinkage. See [smooth.terms](#) for details and full list. User defined bases can also be used here (see [smooth.construct](#) for an example). If only one basis code is given then this is used for all bases.
- `m` The order of the spline and its penalty (for smooth classes that use this) for each term. If a single number is given then it is used for all terms. A vector can be used to supply a different `m` for each margin. For marginals that take vector `m` (e.g. [p.spline](#) and [Duchon.spline](#)), then a list can be supplied, with a vector element for each margin. NA autoinitializes. `m` is ignored by some bases (e.g. "cr").
- `d` array of marginal basis dimensions. For example if you want a smooth for 3 covariates made up of a tensor product of a 2 dimensional t.p.r.s. basis and a 1-dimensional basis, then set `d=c(2, 1)`. Incompatibilities between built in basis types and dimension will be resolved by resetting the basis type.
- `by` a numeric or factor variable of the same dimension as each covariate. In the numeric vector case the elements multiply the smooth evaluated at the corresponding covariate values (a 'varying coefficient model' results). In the factor case causes a replicate of the smooth to be produced for each factor level. See [gam.models](#) for further details. May also be a matrix if covariates are matrices: in this case implements linear functional of a smooth (see [gam.models](#) and [linear.functional.terms](#) for details).
- `fx` indicates whether the term is a fixed d.f. regression spline (TRUE) or a penalized regression spline (FALSE).
- `mp` TRUE to use multiple penalties for the smooth. FALSE to use only a single penalty: single penalties are not recommended and are deprecated - they tend to allow only rather wiggly models.
- `np` TRUE to use the 'normal parameterization' for a tensor product smooth. This represents any 1-d marginal smooths via parameters that are function values at 'knots', spread evenly through the data. The parameterization makes the penalties easily interpretable, however it can reduce numerical stability in some cases.
- `xt` Either a single object, providing any extra information to be passed to each marginal basis constructor, or a list of such objects, one for each marginal basis.

|    |   |
|----|---|
| id | A label or integer identifying this term in order to link its smoothing parameters to others of the same type. If two or more smooth terms have the same id then they will have the same smoothing parameters, and, by default, the same bases (first occurrence defines basis type, but data from all terms used in basis construction).   |
| sp | any supplied smoothing parameters for this term. Must be an array of the same length as the number of penalties for this smooth. Positive or zero elements are taken as fixed smoothing parameters. Negative elements signal auto-initialization. Over-rides values supplied in sp argument to <code>gam</code> . Ignored by <code>gamm</code> .  |
| mc | For <code>ti</code> smooths you can specify which marginals should have centering constraints applied, by supplying 0/1 or FALSE/TRUE values for each marginal in this vector. By default all marginals are constrained, which is what is appropriate for, e.g., functional ANOVA models. Note that ' <code>ti</code> ' only applies constraints to the marginals, so if you turn off all marginal constraints the term will have no identifiability constraints. Only use this if you really understand how marginal constraints work. |
| pc | If not NULL, signals a point constraint: the smooth should pass through zero at the point given here (as a vector or list with names corresponding to the smooth names). Never ignored if supplied. See <a href="#">identifiability</a> .   |

## Details

Smooths of several covariates can be constructed from tensor products of the bases used to represent smooths of one (or sometimes more) of the covariates. To do this 'marginal' bases are produced with associated model matrices and penalty matrices, and these are then combined in the manner described in [tensor.prod.model.matrix](#) and [tensor.prod.penalties](#), to produce a single model matrix for the smooth, but multiple penalties (one for each marginal basis). The basis dimension of the whole smooth is the product of the basis dimensions of the marginal smooths.

An option for operating with a single penalty (The Kronecker product of the marginal penalties) is provided, but it is rarely of practical use, and is deprecated: the penalty is typically so rank deficient that even the smoothest resulting model will have rather high estimated degrees of freedom.

Tensor product smooths are especially useful for representing functions of covariates measured in different units, although they are typically not quite as nicely behaved as t.p.r.s. smooths for well scaled covariates.

It is sometimes useful to investigate smooth models with a main-effects + interactions structure, for example

$$f_1(x) + f_2(z) + f_3(x, z)$$

This functional ANOVA decomposition is supported by `ti` terms, which produce tensor product interactions from which the main effects have been excluded, under the assumption that they will be included separately. For example the `~ ti(x) + ti(z) + ti(x, z)` would produce the above main effects + interaction structure. This is much better than attempting the same thing with `sor` terms representing the interactions (although `mgcv` does not forbid it). Technically `ti` terms are very simple: they simply construct tensor product bases from marginal smooths to which identifiability constraints (usually sum-to-zero) have already been applied: correct nesting is then automatic (as with all interactions in a GLM framework).

The 'normal parameterization' (`np=TRUE`) re-parameterizes the marginal smooths of a tensor product smooth so that the parameters are function values at a set of points spread evenly through the range of values of the covariate of the smooth. This means that the penalty of the tensor product associated with any particular covariate direction can be interpreted as the penalty of the appropriate

marginal smooth applied in that direction and averaged over the smooth. Currently this is only done for marginals of a single variable. This parameterization can reduce numerical stability when used with marginal smooths other than "cc", "cr" and "cs": if this causes problems, set np=FALSE.

Note that tensor product smooths should not be centred (have identifiability constraints imposed) if any marginals would not need centering. The constructor for tensor product smooths ensures that this happens.

The function does not evaluate the variable arguments.

## Value

A class `tensor.smooth.spec` object defining a tensor product smooth to be turned into a basis and penalties by the `smooth.construct.tensor.smooth.spec` function.

The returned object contains the following items:

|                     |   |
|---------------------|---|
| <code>margin</code> | A list of <code>smooth.spec</code> objects of the type returned by <code>s</code> , defining the basis from which the tensor product smooth is constructed.       |
| <code>term</code>   | An array of text strings giving the names of the covariates that the term is a function of.   |
| <code>by</code>     | is the name of any by variable as text ("NA" for none).   |
| <code>fx</code>     | logical array with element for each penalty of the term (tensor product smooths have multiple penalties). TRUE if the penalty is to be ignored, FALSE, otherwise. |
| <code>label</code>  | A suitable text label for this smooth term.   |
| <code>dim</code>    | The dimension of the smoother - i.e. the number of covariates that it is a function of.   |
| <code>mp</code>     | TRUE is multiple penalties are to be used (default).  |
| <code>np</code>     | TRUE to re-parameterize 1-D marginal smooths in terms of function values (default).   |
| <code>id</code>     | the <code>id</code> argument supplied to <code>te</code> .  |
| <code>sp</code>     | the <code>sp</code> argument supplied to <code>te</code> .  |
| <code>inter</code>  | TRUE if the term was generated by <code>ti</code> , FALSE otherwise.  |
| <code>mc</code>     | the argument <code>mc</code> supplied to <code>ti</code> .  |

---

```
tensor.prod.model.matrix
```

*Utility functions for constructing tensor product smooths*

---

## Description

Produce model matrices or penalty matrices for a tensor product smooth from the model matrices or penalty matrices for the marginal bases of the smooth.

## Usage

```
tensor.prod.model.matrix(X)
tensor.prod.penalties(S)
```

## Arguments

|   |   |
|---|---|
| X | a list of model matrices for the marginal bases of a smooth |
| S | a list of penalties for the marginal bases of a smooth.     |

## Details

If  $X[[1]]$ ,  $X[[2]]$  ...  $X[[m]]$  are the model matrices of the marginal bases of a tensor product smooth then the  $i$ th row of the model matrix for the whole tensor product smooth is given by  $X[[1]][i,] \%x\% X[[2]][i,] \%x\% \dots X[[m]][i,]$ , where  $\%x\%$  is the Kronecker product. Of course the routine operates column-wise, not row-wise!

If  $S[[1]]$ ,  $S[[2]]$  ...  $S[[m]]$  are the penalty matrices for the marginal bases, and  $I[[1]]$ ,  $I[[2]]$  ...  $I[[m]]$  are corresponding identity matrices, each of the same dimension as its corresponding penalty, then the tensor product smooth has  $m$  associate penalties of the form:

```
S[[1]] \%x\% I[[2]] \%x\% \dots I[[m]],
I[[1]] \%x\% S[[2]] \%x\% \dots I[[m]]
...
I[[1]] \%x\% I[[2]] \%x\% \dots S[[m]].
```

Of course it's important that the model matrices and penalty matrices are presented in the same order when constructing tensor product smooths.

## Value

Either a single model matrix for a tensor product smooth, or a list of penalty terms for a tensor product smooth.

## Author(s)

Simon N. Wood <simon.wood@r-project.org>

trichol

*Choleski decomposition of a tri-diagonal matrix***Description**

Computes Choleski decomposition of a (symmetric positive definite) tri-diagonal matrix stored as a leading diagonal and sub/super diagonal.

**Usage**

```
trichol(ld,sd)
```

**Arguments**

|    |                              |
|----|------------------------------|
| ld | leading diagonal of matrix   |
| sd | sub-super diagonal of matrix |

**Details**

Calls `dpttrf` from LAPACK. The point of this is that it has  $O(n)$  computational cost, rather than the  $O(n^3)$  required by dense matrix methods.

**Value**

A list with elements `ld` and `sd`. `ld` is the leading diagonal and `sd` is the super diagonal of bidiagonal matrix  $\mathbf{B}$  where  $\mathbf{B}^T \mathbf{B} = \mathbf{T}$  and  $\mathbf{T}$  is the original tridiagonal matrix.

**Author(s)**

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

**References**

**See Also**

[bandchol](#)

**Examples**

```
require(mgcv)
## simulate some diagonals...
set.seed(19); k <- 7
ld <- runif(k)+1
sd <- runif(k-1) -.5

## get diagonals of chol factor...
trichol(ld,sd)

## compare to dense matrix result...
A <- diag(ld);for (i in 1:(k-1)) A[i,i+1] <- A[i+1,i] <- sd[i]
R <- chol(A)
diag(R);diag(R[,-1])
```

trind.generator

*Generates index arrays for upper triangular storage***Description**

Generates index arrays for upper triangular storage up to order four. Useful when working with higher order derivatives, which generate symmetric arrays. Mainly intended for internal use.

**Usage**

```
trind.generator(K = 2)
```

**Arguments**

K                      positive integer determining the size of the array.

**Details**

Suppose that  $m=1$  and you fill an array using code like `for(i in 1:K) for(j in i:K) for(k in j:K) for(l in k:K) {a[,m] <- something; m <- m+1 }` and do this because actually the same "something" would be stored for any permutation of the indices  $i,j,k,l$ . Clearly in storage we have the restriction  $l \geq k \geq j \geq i$ , but for access we want no restriction on the indices. `i4[i,j,k,l]` produces the appropriate  $m$  for unrestricted indices. `i3` and `i2` do the same for 3d and 2d arrays.

**Value**

A list where the entries `i1` to `i4` are arrays in up to four dimensions, containing  $K$  indexes along each dimension.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>.

Examples

```
library(mgcv)
A <- trind.generator(3)

# All permutations of c(1, 2, 3) point to the same index (5)
A$13[1, 2, 3]
A$13[2, 1, 3]
A$13[2, 3, 1]
A$13[3, 1, 2]
A$13[1, 3, 2]
```

---

|         |                             |
|---------|-----------------------------|
| Tweedie | <i>GAM Tweedie families</i> |
|---------|-----------------------------|

---

Description

Tweedie families, designed for use with [gam](#) from the [mgcv](#) library. Restricted to variance function powers between 1 and 2. A useful alternative to [quasi](#) when a full likelihood is desirable. Tweedie is for use with fixed  $p$ . `tw` is for use when  $p$  is to be estimated during fitting. For fixed  $p$  between 1 and 2 the Tweedie is an exponential family distribution with variance given by the mean to the power  $p$ .  
`tw` is only useable with [gam](#), not `bam` or `gamm`. Tweedie works with all three.

Usage

```
Tweedie(p=1, link = power(0))
tw(theta = NULL, link = "log", a=1.01, b=1.99)
```

Arguments

|                    |  |
|--------------------|--|
| <code>p</code>     | the variance of an observation is proportional to its mean to the power $p$ . $p$ must be greater than 1 and less than or equal to 2. 1 would be Poisson, 2 is gamma.  |
| <code>link</code>  | The link function: one of "log", "identity", "inverse", "sqrt", or a <a href="#">power</a> link (Tweedie only).  |
| <code>theta</code> | Related to the Tweedie power parameter by $p = \exp(a + b \exp(\theta)) / (1 + \exp(\theta))$ . If this is supplied as a positive value then it is taken as the fixed value for $p$ . If it is a negative values then its absolute value is taken as the initial value for $p$ . |
| <code>a</code>     | lower limit on $p$ for optimization.   |
| <code>b</code>     | upper limit on $p$ for optimization.   |

Details

A Tweedie random variable with  $1 < p < 2$  is a sum of  $N$  gamma random variables where  $N$  has a Poisson distribution. The  $p=1$  case is a generalization of a Poisson distribution and is a discrete distribution supported on integer multiples of the scale parameter. For  $1 < p < 2$  the distribution is supported on the positive reals with a point mass at zero.  $p=2$  is a gamma distribution. As  $p$  gets very close to 1 the continuous distribution begins to converge on the discretely supported limit at  $p=1$ , and is therefore highly multimodal. See [ldTweedie](#) for more on this behaviour.  
Tweedie is based partly on the [poisson](#) family, and partly on `tweedie` from the `statmod` package. It includes extra components to work with all `mgcv` GAM fitting methods as well as an `aic` function.

The Tweedie density involves a normalizing constant with no closed form, so this is evaluated using the series evaluation method of Dunn and Smyth (2005), with extensions to also compute the derivatives w.r.t.  $p$  and the scale parameter. Without restricting  $p$  to (1,2) the calculation of Tweedie densities is more difficult, and there does not currently seem to be an implementation which offers any benefit over [quasi](#). If you need this case then the `tweedie` package is the place to start.

### Value

For `Tweedie`, an object inheriting from class `family`, with additional elements

|                    |  |
|--------------------|--|
| <code>dvar</code>  | the function giving the first derivative of the variance function w.r.t. $\mu$ .   |
| <code>d2var</code> | the function giving the second derivative of the variance function w.r.t. $\mu$ .  |
| <code>ls</code>    | A function returning a 3 element array: the saturated log likelihood followed by its first 2 derivatives w.r.t. the scale parameter. |

For `tw`, an object of class `extended.family`.

## Simulate data...
dat <- gamSim(1,n=n,dist="poisson",scale=.2)
dat$y <- rTweedie(exp(dat$f),p=1.3,phi=.5) ## Tweedie response

## Fit a fixed p Tweedie, with wrong link ...
b <- gam(y~s(x0)+s(x1)+s(x2)+s(x3),family=Tweedie(1.25,power(.1)),
        data=dat)
plot(b,pages=1)
print(b)

## Same by approximate REML...
b1 <- gam(y~s(x0)+s(x1)+s(x2)+s(x3),family=Tweedie(1.25,power(.1)),
```

```

        data=dat,method="REML")
plot(b1,pages=1)
print(b1)

## estimate p as part of fitting

b2 <- gam(y~s(x0)+s(x1)+s(x2)+s(x3),family=tw(),
        data=dat,method="REML")
plot(b2,pages=1)
print(b2)

rm(dat)

```

uniquecombs

*find the unique rows in a matrix*

## Description

This routine returns a matrix or data frame containing all the unique rows of the matrix or data frame supplied as its argument. That is, all the duplicate rows are stripped out. Note that the ordering of the rows on exit need not be the same as on entry. It also returns an index attribute for relating the result back to the original matrix.

## Usage

```
uniquecombs(x,ordered=FALSE)
```

## Arguments

|                      |   |
|----------------------|---|
| <code>x</code>       | is an R matrix (numeric), or data frame.  |
| <code>ordered</code> | set to TRUE to have the rows of the returned object in the same order regardless of input ordering. |

## Details

Models with more parameters than unique combinations of covariates are not identifiable. This routine provides a means of evaluating the number of unique combinations of covariates in a model.

When `x` has only one column then the routine uses `unique` and `match` to get the index. When there are multiple columns then it uses `paste0` to produce labels for each row, which should be unique if the row is unique. Then `unique` and `match` can be used as in the single column case. Obviously the pasting is inefficient, but still quicker for large `n` than the C based code that used to be called by this routine, which had  $O(n \log(n))$  cost. In principle a hash table based solution in C would be only  $O(n)$  and much quicker in the multicolumn case.

`unique` and `duplicated`, can be used in place of this, if the full index is not needed. Relative performance is variable.

If `x` is not a matrix or data frame on entry then an attempt is made to coerce it to a data frame.

## Value

A matrix or data frame consisting of the unique rows of `x` (in arbitrary order).

The matrix or data frame has an "index" attribute. `index[i]` gives the row of the returned matrix that contains row `i` of the original matrix.

**WARNINGS**

If a dataframe contains variables of a type other than numeric, logical, factor or character, which either have no `as.character` method, or whose `as.character` method is a many to one mapping, then the routine is likely to fail.

If the character representation of a dataframe variable (other than of class factor or character) contains `*` then in principle the method could fail (but with a warning).

**Author(s)**

Simon N. Wood <simon.wood@r-project.org> with thanks to Jonathan Rougier

**See Also**

[unique](#), [duplicated](#), [match](#).

**Examples**

```
require(mgcv)

## matrix example...
X <- matrix(c(1,2,3,1,2,3,4,5,6,1,3,2,4,5,6,1,1,1),6,3,byrow=TRUE)
print(X)
Xu <- uniquecombs(X);Xu
ind <- attr(Xu,"index")
## find the value for row 3 of the original from Xu
Xu[ind[3],];X[3,]

## same with fixed output ordering
Xu <- uniquecombs(X,TRUE);Xu
ind <- attr(Xu,"index")
## find the value for row 3 of the original from Xu
Xu[ind[3],];X[3,]

## data frame example...
df <- data.frame(f=factor(c("er",3,"b","er",3,3,1,2,"b")),
  x=c(.5,1,1.4,.5,1,.6,4,3,1.7),
  bb = c(rep(TRUE,5),rep(FALSE,4)),
  fred = c("foo","a","b","foo","a","vf","er","r","g"),
  stringsAsFactors=FALSE)
uniquecombs(df)
```

---

vcov.gam

---

*Extract parameter (estimator) covariance matrix from GAM fit*

---

**Description**

Extracts the Bayesian posterior covariance matrix of the parameters or frequentist covariance matrix of the parameter estimators from a fitted gam object.

**Usage**

```
## S3 method for class 'gam'
vcov(object, freq = FALSE, dispersion = NULL, unconditional=FALSE, ...)
```

**Arguments**

|               |   |
|---------------|---|
| object        | fitted model object of class gam as produced by gam().  |
| freq          | TRUE to return the frequentist covariance matrix of the parameter estimators, FALSE to return the Bayesian posterior covariance matrix of the parameters. |
| dispersion    | a value for the dispersion parameter: not normally used.  |
| unconditional | if TRUE (and freq==FALSE) then the Bayesian smoothing parameter uncertainty corrected covariance matrix is returned, if available.                        |
| ...           | other arguments, currently ignored.   |

**Details**

Basically, just extracts object\$Ve or object\$Vp from a [gamObject](#).

**Value**

A matrix corresponding to the estimated frequentist covariance matrix of the model parameter estimators/coefficients, or the estimated posterior covariance matrix of the parameters, depending on the argument freq.

**Author(s)**

Henric Nilsson. Maintained by Simon N. Wood <simon.wood@r-project.org>

**References**

Wood, S.N. (2006) On confidence intervals for generalized additive models based on penalized regression splines. Australian and New Zealand Journal of Statistics. 48(4): 445-464.

**See Also**

[gam](#)

**Examples**

```
require(mgcv)
n <- 100
x <- runif(n)
y <- sin(x*2*pi) + rnorm(n)*.2
mod <- gam(y~s(x,bs="cc",k=10),knots=list(x=seq(0,1,length=10)))
diag(vcov(mod))
```

**Description**

Produces perspective or contour plot views of gam model predictions, fixing all but the values in view to the values supplied in cond.

**Usage**

```
vis.gam(x, view=NULL, cond=list(), n.grid=30, too.far=0, col=NA,
        color="heat", contour.col=NULL, se=-1, type="link",
        plot.type="persp", zlim=NULL, nCol=50, ...)
```

**Arguments**

|                          |   |
|--------------------------|---|
| <code>x</code>           | a gam object, produced by <code>gam()</code>  |
| <code>view</code>        | an array containing the names of the two main effect terms to be displayed on the x and y dimensions of the plot. If omitted the first two suitable terms will be used. Note that variables coerced to factors in the model formula won't work as view variables, and <code>vis.gam</code> can not detect that this has happened when setting defaults.                                     |
| <code>cond</code>        | a named list of the values to use for the other predictor terms (not in <code>view</code> ). Variables omitted from this list will have the closest observed value to the median for continuous variables, or the most commonly occurring level for factors. Parametric matrix variables have all the entries in each column set to the observed column entry closest to the column median. |
| <code>n.grid</code>      | The number of grid nodes in each direction used for calculating the plotted surface.  |
| <code>too.far</code>     | plot grid nodes that are too far from the points defined by the variables given in <code>view</code> can be excluded from the plot. <code>too.far</code> determines what is too far. The grid is scaled into the unit square along with the view variables and then grid nodes more than <code>too.far</code> from the predictor variables are excluded.                                    |
| <code>col</code>         | The colours for the facets of the plot. If this is NA then if <code>se&gt;0</code> the facets are transparent, otherwise the colour scheme specified in <code>color</code> is used. If <code>col</code> is not NA then it is used as the facet colour.  |
| <code>color</code>       | the colour scheme to use for plots when <code>se&lt;=0</code> . One of "topo", "heat", "cm", "terrain", "gray" or "bw". Schemes "gray" and "bw" also modify the colors used when <code>se&gt;0</code> .   |
| <code>contour.col</code> | sets the colour of contours when using <code>plot.type="contour"</code> . Default scheme used if NULL.  |
| <code>se</code>          | if less than or equal to zero then only the predicted surface is plotted, but if greater than zero, then 3 surfaces are plotted, one at the predicted values minus <code>se</code> standard errors, one at the predicted values and one at the predicted values plus <code>se</code> standard errors.   |
| <code>type</code>        | "link" to plot on linear predictor scale and "response" to plot on the response scale.  |
| <code>plot.type</code>   | one of "contour" or "persp".  |
| <code>zlim</code>        | a two item array giving the lower and upper limits for the z-axis scale. NULL to choose automatically.  |
| <code>nCol</code>        | The number of colors to use in color schemes.   |
| <code>...</code>         | other options to pass on to <code>persp</code> , <code>image</code> or <code>contour</code> . In particular <code>ticktype="detailed"</code> will add proper axes labelling to the plots.   |

## Details

The x and y limits are determined by the ranges of the terms named in `view`. If `se<=0` then a single (height colour coded, by default) surface is produced, otherwise three (by default see-through) meshes are produced at mean and  $\pm$  se standard errors. Parts of the x-y plane too far from data can be excluded by setting `too.far`

All options to the underlying graphics functions can be reset by passing them as extra arguments ...: such supplied values will always over-ride the default values used by `vis.gam`.

## Value

Simply produces a plot.

## WARNINGS

The routine can not detect that a variable has been coerced to factor within a model formula, and will therefore fail if such a variable is used as a view variable. When setting default view variables it can not detect this situation either, which can cause failures if the coerced variables are the first, otherwise suitable, variables encountered.

---

ziP

*GAM zero-inflated Poisson regression family*

---

## Description

Family for use with [gam](#), implementing regression for zero inflated Poisson data when the complementary log log of the zero probability is linearly dependent on the log of the Poisson parameter. Use with great care, noting that simply having many zero response observations is not an indication of zero inflation: the question is whether you have too many zeroes given the specified model.

This sort of model is really only appropriate when none of your covariates help to explain the zeroes in your data. If your covariates predict which observations are likely to have zero mean then adding a zero inflated model on top of this is likely to lead to identifiability problems. Identifiability problems may lead to fit failures, or absurd values for the linear predictor or predicted values.

## Usage

```
ziP(theta = NULL, link = "identity",b=0)
```

## Arguments

|       |  |
|-------|--|
| theta | the 2 parameters controlling the slope and intercept of the linear transform of the mean controlling the zero inflation rate. If supplied then treated as fixed parameters ( $\theta_1$ and $\theta_2$ ), otherwise estimated. |
| link  | The link function: only the "identity" is currently supported.   |
| b     | a non-negative constant, specifying the minimum dependence of the zero inflation rate on the linear predictor.   |

## Details

The probability of a zero count is given by  $1 - p$ , whereas the probability of count  $y > 0$  is given by the truncated Poisson probability function  $p\mu^y/((\exp(\mu) - 1)y!)$ . The linear predictor gives  $\log \mu$ , while  $\eta = \log(-\log(1 - p))$  and  $\eta = \theta_1 + \{b + \exp(\theta_2)\} \log \mu$ . The theta parameters are estimated alongside the smoothing parameters. Increasing the b parameter from zero can greatly reduce identifiability problems, particularly when there are very few non-zero data.

The fitted values for this model are the log of the Poisson parameter. Use the predict function with type=="response" to get the predicted expected response. Note that the theta parameters reported in model summaries are  $\theta_1$  and  $b + \exp(\theta_2)$ .

These models should be subject to very careful checking, especially if fitting has not converged. It is quite easy to set up models with identifiability problems, particularly if the data are not really zero inflated, but simply have many zeroes because the mean is very low in some parts of the covariate space. See example for some obvious checks. Take convergence warnings seriously.

## Value

An object of class extended.family.

## WARNINGS

Zero inflated models are often over-used. Having lots of zeroes in the data does not in itself imply zero inflation. Having too many zeroes \*given the model mean\* may imply zero inflation.

```

---

ziplss

*Zero inflated Poisson location-scale model family*

---

## Description

The `ziplss` family implements a zero inflated Poisson model in which one linear predictor controls the probability of presence and the other controls the mean given presence. Useable only with [gam](#), the linear predictors are specified via a list of formulae. Should be used with care: simply having a large number of zeroes is not an indication of zero inflation.

Requires integer count data.

## Usage

```
ziplss(link=list("identity","identity"))
```

## Arguments

`link` two item list specifying the link - currently only identity links are possible, as parameterization is directly in terms of log of Poisson response and logit of probability of presence.

## Details

Used with `gam` to fit 2 stage zero inflated Poisson models. `gam` is called with a list containing 2 formulae, the first specifies the response on the left hand side and the structure of the linear predictor for the Poisson parameter on the right hand side. The second is one sided, specifying the linear predictor for the probability of presence on the right hand side.

The fitted values for this family will be a two column matrix. The first column is the log of the Poisson parameter, and the second column is the complimentary log log of probability of presence.. Predictions using `predict.gam` will also produce 2 column matrices for type "link" and "response".

The null deviance computed for this model assumes that a single probability of presence and a single Poisson parameter are estimated.

For data with large areas of covariate space over which the response is zero it may be advisable to use low order penalties to avoid problems. For 1D smooths uses e.g. `s(x,m=1)` and for isotropic smooths use `Duchon.splines` in place of thin plate terms with order 1 penalties, e.g. `s(x,z,m=c(1,.5))` — such smooths penalize towards constants, thereby avoiding extreme estimates when the data are uninformative.

## Value

An object inheriting from class `general.family`.

## WARNINGS

Zero inflated models are often over-used. Having lots of zeroes in the data does not in itself imply zero inflation. Having too many zeroes \*given the model mean\* may imply zero inflation.

## Chapter 25

# The nlme package

---

ACF

*Autocorrelation Function*

---

### Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `gls` and `lme`.

### Usage

```
ACF(object, maxLag, ...)
```

### Arguments

|                     |   |
|---------------------|---|
| <code>object</code> | any object from which an autocorrelation function can be obtained. Generally an object resulting from a model fit, from which residuals can be extracted. |
| <code>maxLag</code> | maximum lag for which the autocorrelation should be calculated.   |
| <code>...</code>    | some methods for this generic require additional arguments.   |

### Value

will depend on the method function used; see the appropriate documentation.

### Author(s)

José Pinheiro and Douglas Bates <Bates@stat.wisc.edu>

### References

Box, G.E.P., Jenkins, G.M., and Reinsel G.C. (1994) "Time Series Analysis: Forecasting and Control", 3rd Edition, Holden-Day.

ACF.gls

*Autocorrelation Function for gls Residuals*

---

## Description

This method function calculates the empirical autocorrelation function for the residuals from a gls fit. If a grouping variable is specified in form, the autocorrelation values are calculated using pairs of residuals within the same group; otherwise all possible residual pairs are used. The autocorrelation function is useful for investigating serial correlation models for equally spaced data.

## Usage

```
## S3 method for class 'gls'
ACF(object, maxLag, resType, form, na.action, ...)
```

## Arguments

|           |  |
|-----------|--|
| object    | an object inheriting from class "gls", representing a generalized least squares fitted model.  |
| maxLag    | an optional integer giving the maximum lag for which the autocorrelation should be calculated. Defaults to maximum lag in the residuals.   |
| resType   | an optional character string specifying the type of residuals to be used. If "response", the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson". |
| form      | an optional one sided formula of the form $\sim t$ , or $\sim t   g$ , specifying a time covariate $t$ and, optionally, a grouping factor $g$ . The time covariate must be integer valued. When a grouping factor is present in form, the autocorrelations are calculated using residual pairs within the same group. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups.   |
| na.action | a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes ACF.gls to print an error message and terminate if there are any incomplete observations.  |
| ...       | some methods for this generic require additional arguments.  |

## Value

a data frame with columns lag and ACF representing, respectively, the lag between residuals within a pair and the corresponding empirical autocorrelation. The returned value inherits from class ACF.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

ACF.lme

---

Autocorrelation Function for lme Residuals

---

## Description

This method function calculates the empirical autocorrelation function for the within-group residuals from an lme fit. The autocorrelation values are calculated using pairs of residuals within the innermost group level. The autocorrelation function is useful for investigating serial correlation models for equally spaced data.

## Usage

```
## S3 method for class 'lme'
ACF(object, maxLag, resType, ...)
```

## Arguments

|         |  |
|---------|--|
| object  | an object inheriting from class " <a href="#">lme</a> ", representing a fitted linear mixed-effects model.   |
| maxLag  | an optional integer giving the maximum lag for which the autocorrelation should be calculated. Defaults to maximum lag in the within-group residuals.  |
| resType | an optional character string specifying the type of residuals to be used. If "response", the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson". |
| ...     | some methods for this generic require additional arguments – not used.   |

**Value**

a data frame with columns lag and ACF representing, respectively, the lag between residuals within a pair and the corresponding empirical autocorrelation. The returned value inherits from class ACF.

Alfalfa

*Split-Plot Experiment on Varieties of Alfalfa*

---

**Description**

The Alfalfa data frame has 72 rows and 4 columns.

**Format**

This data frame contains the following columns:

**Variety** a factor with levels Cossack, Ladak, and Ranger

**Date** a factor with levels None S1 S20 07

**Block** a factor with levels 1 2 3 4 5 6

**Yield** a numeric vector

## Details

These data are described in Snedecor and Cochran (1980) as an example of a split-plot design. The treatment structure used in the experiment was a  $3 \times 4$  full factorial, with three varieties of alfalfa and four dates of third cutting in 1943. The experimental units were arranged into six blocks, each subdivided into four plots. The varieties of alfalfa (*Cossac*, *Ladak*, and *Ranger*) were assigned randomly to the blocks and the dates of third cutting (*None*, *S1*—September 1, *S20*—September 20, and *O7*—October 7) were randomly assigned to the plots. All four dates were used on each block.

allCoef

---

*Extract Coefficients from a Set of Objects*

---

## Description

The extractor function is applied to each object in `...`, with the result being converted to a vector. A map attribute is included to indicate which pieces of the returned vector correspond to the original objects in dots.

## Usage

```
allCoef(..., extract)
```

## Arguments

|                      |  |
|----------------------|--|
| <code>...</code>     | objects to which extract will be applied. Generally these will be model components, such as <code>corStruct</code> and <code>varFunc</code> objects. |
| <code>extract</code> | an optional extractor function. Defaults to <code>coef</code> .  |

## Value

a vector with all elements, generally coefficients, obtained by applying `extract` to the objects in `...`

anova.gls

*Compare Likelihoods of Fitted Objects***Description**

When only one fitted model object is present, a data frame with the sums of squares, numerator degrees of freedom, F-values, and P-values for Wald tests for the terms in the model (when Terms and L are NULL), a combination of model terms (when Terms is not NULL), or linear combinations of the model coefficients (when L is not NULL). Otherwise, when multiple fitted objects are being compared, a data frame with the degrees of freedom, the (restricted) log-likelihood, the Akaike Information Criterion (AIC), and the Bayesian Information Criterion (BIC) of each object is returned. If test=TRUE, whenever two consecutive objects have different number of degrees of freedom, a likelihood ratio statistic, with the associated p-value is included in the returned data frame.

**Usage**

```
## S3 method for class 'glS'
anova(object, ..., test, type, adjustSigma, Terms, L, verbose)
```

**Arguments**

- |             |  |
|-------------|--|
| object      | a fitted model object inheriting from class gls, representing a generalized least squares fit.   |
| ...         | other optional fitted model objects inheriting from classes "glS", "gnls", "lm", "lme", "lmList", "nlme", "nlsList", or "nls".   |
| test        | an optional logical value controlling whether likelihood ratio tests should be used to compare the fitted models represented by object and the objects in .... Defaults to TRUE.   |
| type        | an optional character string specifying the type of sum of squares to be used in F-tests for the terms in the model. If "sequential", the sequential sum of squares obtained by including the terms in the order they appear in the model is used; else, if "marginal", the marginal sum of squares obtained by deleting a term from the model at a time is used. This argument is only used when a single fitted object is passed to the function. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "sequential". |
| adjustSigma | an optional logical value. If TRUE and the estimation method used to obtain object was maximum likelihood, the residual standard error is multiplied by $\sqrt{n_{obs}/(n_{obs} - n_{par})}$ , converting it to a REML-like estimate. This argument is only used when a single fitted object is passed to the function. Default is TRUE.   |
| Terms       | an optional integer or character vector specifying which terms in the model should be jointly tested to be zero using a Wald F-test. If given as a character vector, its elements must correspond to term names; else, if given as an integer vector, its elements must correspond to the order in which terms are included in the model. This argument is only used when a single fitted object is passed to the function. Default is NULL.   |
| L           | an optional numeric vector or array specifying linear combinations of the coefficients in the model that should be tested to be zero. If given as an array, its rows define the linear combinations to be tested. If names are assigned to the vector elements (array columns), they must correspond to coefficients names and will  |

be used to map the linear combination(s) to the coefficients; else, if no names are available, the vector elements (array columns) are assumed in the same order as the coefficients appear in the model. This argument is only used when a single fitted object is passed to the function. Default is NULL.

**verbose** an optional logical value. If TRUE, the calling sequences for each fitted model object are printed with the rest of the output, being omitted if verbose = FALSE. Defaults to FALSE.

### Value

a data frame inheriting from class "anova.lme".

### Note

Likelihood comparisons are not meaningful for objects fit using restricted maximum likelihood and with different fixed effects.

If "sequential", the sequential sum of squares obtained by including the terms in the order they appear in the model is used; else, if "marginal", the marginal sum of squares obtained by deleting a term from the model at a time is used. This argument is only used when a single fitted object is passed to the function. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "sequential".   |
| adjustSigma | an optional logical value. If TRUE and the estimation method used to obtain object was maximum likelihood, the residual standard error is multiplied by $\sqrt{n_{obs}/(n_{obs} - n_{par})}$ , converting it to a REML-like estimate. This argument is only used when a single fitted object is passed to the function. Default is TRUE.   |
| Terms       | an optional integer or character vector specifying which terms in the model should be jointly tested to be zero using a Wald F-test. If given as a character vector, its elements must correspond to term names; else, if given as an integer vector, its elements must correspond to the order in which terms are included in the model. This argument is only used when a single fitted object is passed to the function. Default is NULL.   |
| L           | an optional numeric vector or array specifying linear combinations of the coefficients in the model that should be tested to be zero. If given as an array, its rows define the linear combinations to be tested. If names are assigned to the vector elements (array columns), they must correspond to coefficients names and will be used to map the linear combination(s) to the coefficients; else, if no names are available, the vector elements (array columns) are assumed in the same order as the coefficients appear in the model. This argument is only used when a single fitted object is passed to the function. Default is NULL. |
| x           | an object inheriting from class "anova.lme"  |
| verbose     | an optional logical value. If TRUE, the calling sequences for each fitted model object are printed with the rest of the output, being omitted if verbose = FALSE. Defaults to FALSE.   |

**Value**

a data frame inheriting from class "anova.lme".

**Note**

Likelihood comparisons are not meaningful for objects fit using restricted maximum likelihood and with different fixed effects.

---

as.matrix.corStruct     *Matrix of a corStruct Object*

---

## Description

This method function extracts the correlation matrix, or list of correlation matrices, associated with object.

**Usage**

```
## S3 method for class 'corStruct'
as.matrix(x, ...)
```

**Arguments**

**x** an object inheriting from class "[corStruct](#)", representing a correlation structure.

**...** further arguments passed from other methods.

**Value**

If the correlation structure includes a grouping factor, the returned value will be a list with components given by the correlation matrices for each group. Otherwise, the returned value will be a matrix representing the correlation structure associated with object.

|       |                                       |
|-------|---------------------------------------|
| Assay | <i>Bioassay on Cell Culture Plate</i> |
|-------|---------------------------------------|

---

### Description

The Assay data frame has 60 rows and 4 columns.

### Format

This data frame contains the following columns:

**Block** an ordered factor with levels 2 < 1 identifying the block where the wells are measured.

**sample** a factor with levels a to f identifying the sample corresponding to the well.

**dilut** a factor with levels 1 to 5 indicating the dilution applied to the well

**logDens** a numeric vector of the log-optical density

### Details

These data, courtesy of Rich Wolfe and David Lansky from Searle, Inc., come from a bioassay run on a 96-well cell culture plate. The assay is performed using a split-block design. The 8 rows on the plate are labeled A–H from top to bottom and the 12 columns on the plate are labeled 1–12 from left to right. Only the central 60 wells of the plate are used for the bioassay (the intersection of rows B–G and columns 2–11). There are two blocks in the design: Block 1 contains columns 2–6 and Block 2 contains columns 7–11. Within each block, six samples are assigned randomly to rows and five (serial) dilutions are assigned randomly to columns. The response variable is the logarithm of the optical density. The cells are treated with a compound that they metabolize to produce the stain. Only live cells can make the stain, so the optical density is a measure of the number of cells that are alive and healthy.

---

|         |  |
|---------|--|
| asTable | <i>Convert groupedData to a matrix</i> |
|---------|--|

---

### Description

Create a tabular representation of the response in a balanced groupedData object.

### Usage

```
asTable(object)
```

### Arguments

**object** A balanced groupedData object

**Details**

A balanced groupedData object can be represented as a matrix or table of response values corresponding to the values of a primary covariate for each level of a grouping factor. This function creates such a matrix representation of the data in object.

**Value**

A matrix. The data in the matrix are the values of the response. The columns correspond to the distinct values of the primary covariate and are labelled as such. The rows correspond to the distinct levels of the grouping factor and are labelled as such.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

Pinheiro, J. C. and Bates, D. M. (2000), *Mixed-Effects Models in S and S-PLUS*, Springer, New York.

**See Also**

[groupedData](#), [isBalanced](#), [balancedGrouped](#)

**Examples**

```
asTable(Orthodont)

# Pinheiro and Bates, p. 109
ergoStool.mat <- asTable(ergoStool)
```

---

augPred

---

*Augmented Predictions*

---

**Description**

Predicted values are obtained at the specified values of primary. If object has a grouping structure (i.e. `getGroups(object)` is not NULL), predicted values are obtained for each group. If level has more than one element, predictions are obtained for each level of the `max(level)` grouping factor. If other covariates besides primary are used in the prediction model, their average (numeric covariates) or most frequent value (categorical covariates) are used to obtain the predicted values. The original observations are also included in the returned object.

**Usage**

```
augPred(object, primary, minimum, maximum, length.out, ...)

## S3 method for class 'lme'
augPred(object, primary = NULL,
        minimum = min(primary), maximum = max(primary),
        length.out = 51, level = Q, ...)
```

**Arguments**

|            |  |
|------------|--|
| object     | a fitted model object from which predictions can be extracted, using a predict method.   |
| primary    | an optional one-sided formula specifying the primary covariate to be used to generate the augmented predictions. By default, if a covariate can be extracted from the data used to generate object (using getCovariate), it will be used as primary. |
| minimum    | an optional lower limit for the primary covariate. Defaults to min(primary).   |
| maximum    | an optional upper limit for the primary covariate. Defaults to max(primary).   |
| length.out | an optional integer with the number of primary covariate values at which to evaluate the predictions. Defaults to 51.  |
| level      | an optional integer vector specifying the desired prediction levels. Levels increase from outermost to innermost grouping, with level 0 representing the population (fixed effects) predictions. Defaults to the innermost level.                    |
| ...        | some methods for the generic may require additional arguments.   |

**Value**

a data frame with four columns representing, respectively, the values of the primary covariate, the groups (if object does not have a grouping structure, all elements will be 1), the predicted or observed values, and the type of value in the third column: original for the observed values and predicted (single or no grouping factor) or predict.groupVar (multiple levels of grouping), with groupVar replaced by the actual grouping variable name (fixed is used for population predictions). The returned object inherits from class "augPred".

**Note**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: gls, lme, and lmList.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

fm1 <- lme(Orthodont, random = ~1)
augPred(fm1, length.out = 2, level = c(0,1))
```

---

|                 |   |
|-----------------|---|
| balancedGrouped | Create a groupedData object from a matrix |
|-----------------|---|

---

## Description

Create a groupedData object from a data matrix. This function can be used only with balanced data. The opposite conversion, from a groupedData object to a matrix, is done with asTable.

## Usage

```
balancedGrouped(form, data, labels=NULL, units=NULL)
```

## Arguments

|        |  |
|--------|--|
| form   | A formula of the form $y \sim x \mid g$ giving the name of the response, the primary covariate, and the grouping factor.   |
| data   | A matrix or data frame containing the values of the response grouped according to the levels of the grouping factor (rows) and the distinct levels of the primary covariate (columns). The dimnames of the matrix are used to construct the levels of the grouping factor and the primary covariate. |
| labels | an optional list of character strings giving labels for the response and the primary covariate. The label for the primary covariate is named x and that for the response is named y. Either label can be omitted.  |
| units  | an optional list of character strings giving the units for the response and the primary covariate. The units string for the primary covariate is named x and that for the response is named y. Either units string can be omitted.   |

## Value

A balanced groupedData object.

## Author(s)

                 data=ergoStool.mat)
```

bdf

*Language scores*

## Description

The bdf data frame has 2287 rows and 25 columns of language scores from grade 8 pupils in elementary schools in The Netherlands.

## Usage

```
data(bdf)
```

## Format

**schoolNR** a factor denoting the school.

**pupilNR** a factor denoting the pupil.

**IQ.verb** a numeric vector of verbal IQ scores

**IQ.perf** a numeric vector of IQ scores.

**sex** Sex of the student.

**Minority** a factor indicating if the student is a member of a minority group.

**repeatgr** an ordered factor indicating if one or more grades have been repeated.

**aritPRET** a numeric vector

**classNR** a numeric vector

**aritPOST** a numeric vector

**langPRET** a numeric vector

**langPOST** a numeric vector

**ses** a numeric vector of socioeconomic status indicators.

**denomina** a factor indicating if the school is a public school, a Protestant private school, a Catholic private school, or a non-denominational private school.

**schoolSES** a numeric vector

**satiprin** a numeric vector

**natitest** a factor with levels 0 and 1

**meetings** a numeric vector

**currmeet** a numeric vector

**mixedgra** a factor indicating if the class is a mixed-grade class.

**percmينو** a numeric vector

**aritdiff** a numeric vector

**homework** a numeric vector

**classsiz** a numeric vector

**groupsiz** a numeric vector

---

|            |   |
|------------|---|
| BodyWeight | <i>Rat weight over time for different diets</i> |
|------------|---|

---

## Description

The BodyWeight data frame has 176 rows and 4 columns.

## Format

This data frame contains the following columns:

**weight** a numeric vector giving the body weight of the rat (grams).

**Time** a numeric vector giving the time at which the measurement is made (days).

**Rat** an ordered factor with levels 2 < 3 < 4 < 1 < 8 < 5 < 6 < 7 < 11 < 9 < 10 < 12 < 13 < 15 < 14 < 16 identifying the rat whose weight is measured.

**Diet** a factor with levels 1 to 3 indicating the diet that the rat receives.

## Details

Hand and Crowder (1996) describe data on the body weights of rats measured over 64 days. These data also appear in Table 2.4 of Crowder and Hand (1990). The body weights of the rats (in grams) are measured on day 1 and every seven days thereafter until day 64, with an extra measurement on day 44. The experiment started several weeks before “day 1.” There are three groups of rats, each on a different diet.

Cefamandole

*Pharmacokinetics of Cefamandole***Description**

The Cefamandole data frame has 84 rows and 3 columns.

**Format**

This data frame contains the following columns:

**Subject** a factor giving the subject from which the sample was drawn.

**Time** a numeric vector giving the time at which the sample was drawn (minutes post-injection).

**conc** a numeric vector giving the observed plasma concentration of cefamandole (mcg/ml).

**Details**

Davidian and Giltinan (1995, 1.1, p. 2) describe data obtained during a pilot study to investigate the pharmacokinetics of the drug cefamandole. Plasma concentrations of the drug were measured on six healthy volunteers at 14 time points following an intravenous dose of 15 mg/kg body weight of cefamandole.

plot(Cefamandole)
fm1 <- nlsList(SSbiexp, data = Cefamandole)
summary(fm1)
```

Coef

*Assign Values to Coefficients***Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all "[pdMat](#)", "[corStruct](#)" and "[varFunc](#)" classes, "[reStruct](#)", and "[modelStruct](#)".

**Usage**

```
coef(object, ...) <- value
```

**Arguments**

|        |   |
|--------|---|
| object | any object representing a fitted model, or, by default, any object with a coef component. |
| ...    | some methods for this generic function may require additional arguments.                  |
| value  | a value to be assigned to the coefficients associated with object.                        |

**Value**

will depend on the method function; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[coef](#)

**Examples**

```
## see the method function documentation
```

---

coef.corStruct

*Coefficients of a corStruct Object*

---

**Description**

This method function extracts the coefficients associated with the correlation structure represented by object.

**Usage**

```
## S3 method for class 'corStruct'
coef(object, unconstrained, ...)
## S3 replacement method for class 'corStruct'
coef(object, ...) <- value
```

**Arguments**

|               |  |
|---------------|--|
| object        | an object inheriting from class " <a href="#">corStruct</a> ", representing a correlation structure.   |
| unconstrained | a logical value. If TRUE the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If FALSE the coefficients are returned in "natural", possibly constrained, form. Defaults to TRUE. |
| value         | a vector with the replacement values for the coefficients associated with object. It must be a vector with the same length of coef{object} and must be given in unconstrained form.  |
| ...           | some methods for this generic require additional arguments. None are used in this method.  |

**Value**

a vector with the coefficients corresponding to object.

**SIDE EFFECTS**

On the left side of an assignment, sets the values of the coefficients of object to value. Object must be initialized (using `Initialize`) before new values can be assigned to its coefficients.

**Author(s)**

José Pinheiro and Douglas Bates

**References**

cst1 <- corARMA(p = 1, q = 1)
coef(cst1)
```

---

coef.gnls

---

*Extract gnls Coefficients*

---

**Description**

The estimated coefficients for the nonlinear model represented by object are extracted.

**Usage**

```
## S3 method for class 'gnls'
coef(object, ...)
```

**Arguments**

|        |  |
|--------|--|
| object | an object inheriting from class " <a href="#">gnls</a> ", representing a generalized nonlinear least squares fitted model. |
| ...    | some methods for this generic require additional arguments. None are used in this method.                                  |

**Value**

a vector with the estimated coefficients for the nonlinear model represented by object.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

[gnls](#)

Examples

```
fm1 <- gnls(weight ~ SSlogis(Time, Asym, xmid, scal), Soybean,
            weights = varPower())
coef(fm1)
```

---

|          |                                 |
|----------|---------------------------------|
| coef.lme | <i>Extract lme Coefficients</i> |
|----------|---------------------------------|

---

Description

The estimated coefficients at level  $i$  are obtained by adding together the fixed effects estimates and the corresponding random effects estimates at grouping levels less or equal to  $i$ . The resulting estimates are returned as a data frame, with rows corresponding to groups and columns to coefficients. Optionally, the returned data frame may be augmented with covariates summarized over groups.

Usage

```
## S3 method for class 'lme'
coef(object, augFrame, level, data, which, FUN,
      omitGroupingFactor, subset, ...)
```

Arguments

|          |  |
|----------|--|
| object   | an object inheriting from class " <a href="#">lme</a> ", representing a fitted linear mixed-effects model.   |
| augFrame | an optional logical value. If TRUE, the returned data frame is augmented with variables defined in data; else, if FALSE, only the coefficients are returned. Defaults to FALSE.  |
| level    | an optional positive integer giving the level of grouping to be used in extracting the coefficients from an object with multiple nested grouping levels. Defaults to the highest or innermost level of grouping.   |
| data     | an optional data frame with the variables to be used for augmenting the returned data frame when augFrame = TRUE. Defaults to the data frame used to fit object.   |
| which    | an optional positive integer or character vector specifying which columns of data should be used in the augmentation of the returned data frame. Defaults to all columns in data.  |
| FUN      | an optional summary function or a list of summary functions to be applied to group-varying variables, when collapsing data by groups. Group-invariant variables are always summarized by the unique value that they assume within that group. If FUN is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If FUN is a list of functions, the names in the list should designate classes of variables in the frame such as ordered, factor, or numeric. The indicated function will be applied to any group-varying variables of that class. The default functions to be used are mean |

for numeric factors, and Mode for both factor and ordered. The Mode function, defined internally in gsummary, returns the modal or most popular value of the variable. It is different from the mode function that returns the S-language mode of the variable.

omitGroupingFactor      an optional logical value. When TRUE the grouping factor itself will be omitted from the group-wise summary of data but the levels of the grouping factor will continue to be used as the row names for the returned data frame. Defaults to FALSE.

subset                    an optional expression specifying a subset

...                        some methods for this generic require additional arguments. None are used in this method.

Value

a data frame inheriting from class "coef.lme" with the estimated coefficients at level level and, optionally, other covariates summarized over groups. The returned object also inherits from classes "ranef.lme" and "data.frame".

---

Description

The coefficients of each lm object in the object list are extracted and organized into a data frame, with rows corresponding to the lm components and columns corresponding to the coefficients. Optionally, the returned data frame may be augmented with covariates summarized over the groups associated with the lm components.

Usage

```
## S3 method for class 'lmList'
coef(object, augFrame, data, which, FUN,
      omitGroupingFactor, ...)
```

**Arguments**

|                    |   |
|--------------------|---|
| object             | an object inheriting from class <code>"lmList"</code> , representing a list of <code>lm</code> objects with a common model.   |
| augFrame           | an optional logical value. If <code>TRUE</code> , the returned data frame is augmented with variables defined in the data frame used to produce object; else, if <code>FALSE</code> , only the coefficients are returned. Defaults to <code>FALSE</code> .  |
| data               | an optional data frame with the variables to be used for augmenting the returned data frame when <code>augFrame = TRUE</code> . Defaults to the data frame used to fit object.  |
| which              | an optional positive integer or character vector specifying which columns of the data frame used to produce object should be used in the augmentation of the returned data frame. Defaults to all variables in the data.  |
| FUN                | an optional summary function or a list of summary functions to be applied to group-varying variables, when collapsing the data by groups. Group-invariant variables are always summarized by the unique value that they assume within that group. If FUN is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If FUN is a list of functions, the names in the list should designate classes of variables in the frame such as <code>ordered</code> , <code>factor</code> , or <code>numeric</code> . The indicated function will be applied to any group-varying variables of that class. The default functions to be used are <code>mean</code> for numeric factors, and <code>Mode</code> for both <code>factor</code> and <code>ordered</code> . The <code>Mode</code> function, defined internally in <code>gsummary</code> , returns the modal or most popular value of the variable. It is different from the <code>mode</code> function that returns the S-language mode of the variable. |
| omitGroupingFactor | an optional logical value. When <code>TRUE</code> the grouping factor itself will be omitted from the group-wise summary of data but the levels of the grouping factor will continue to be used as the row names for the returned data frame. Defaults to <code>FALSE</code> .  |
| ...                | some methods for this generic require additional arguments. None are used in this method.   |

**Value**

a data frame inheriting from class `"coef.lmList"` with the estimated coefficients for each `"lm"` component of object and, optionally, other covariates summarized over the groups corresponding to the `"lm"` components. The returned object also inherits from classes `"ranef.lmList"` and `"data.frame"`.

Examples

```
fm1 <- lmList(distance ~ age|Subject, data = Orthodont)
coef(fm1)
coef(fm1, augFrame = TRUE)
```

---

|                  |  |
|------------------|--|
| coef.modelStruct | <i>Extract modelStruct Object Coefficients</i> |
|------------------|--|

---

Description

This method function extracts the coefficients associated with each component of the modelStruct list.

Usage

```
## S3 method for class 'modelStruct'
coef(object, unconstrained, ...)
## S3 replacement method for class 'modelStruct'
coef(object, ...) <- value
```

Arguments

- object            an object inheriting from class "modelStruct", representing a list of model components, such as "[corStruct](#)" and "[varFunc](#)" objects.
- unconstrained    a logical value. If TRUE the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If FALSE the coefficients are returned in "natural", possibly constrained, form. Defaults to TRUE.
- value            a vector with the replacement values for the coefficients associated with object. It must be a vector with the same length of coef{object} and must be given in unconstrained form.
- ...              some methods for this generic require additional arguments. None are used in this method.

Value

a vector with all coefficients corresponding to the components of object.

SIDE EFFECTS

On the left side of an assignment, sets the values of the coefficients of object to value. Object must be initialized (using [Initialize](#)) before new values can be assigned to its coefficients.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**Examples**

```
lms1 <- lmeStruct(reStruct = reStruct(pdDiag(diag(2), ~age)),
  corStruct = corAR1(0.3))
coef(lms1)
```

coef.pdMat

*pdMat Object Coefficients***Description**

This method function extracts the coefficients associated with the positive-definite matrix represented by object.

**Usage**

```
## S3 method for class 'pdMat'
coef(object, unconstrained, ...)
## S3 replacement method for class 'pdMat'
coef(object, ...) <- value
```

**Arguments**

|               |  |
|---------------|--|
| object        | an object inheriting from class " <a href="#">pdMat</a> ", representing a positive-definite matrix.  |
| unconstrained | a logical value. If TRUE the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If FALSE the upper triangular elements of the positive-definite matrix represented by object are returned. Defaults to TRUE. |
| value         | a vector with the replacement values for the coefficients associated with object. It must be a vector with the same length of <code>coef{object}</code> and must be given in unconstrained form.   |
| ...           | some methods for this generic require additional arguments. None are used in this method.  |

**Value**

a vector with the coefficients corresponding to object.

**SIDE EFFECTS**

On the left side of an assignment, sets the values of the coefficients of object to value.

coef.reStruct

*reStruct Object Coefficients***Description**

This method function extracts the coefficients associated with the positive-definite matrix represented by object.

**Usage**

```
## S3 method for class 'reStruct'
coef(object, unconstrained, ...)
## S3 replacement method for class 'reStruct'
coef(object, ...) <- value
```

**Arguments**

|               |  |
|---------------|--|
| object        | an object inheriting from class " <a href="#">reStruct</a> ", representing a random effects structure and consisting of a list of <a href="#">pdMat</a> objects.   |
| unconstrained | a logical value. If TRUE the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If FALSE the coefficients are returned in "natural", possibly constrained, form. Defaults to TRUE. |
| value         | a vector with the replacement values for the coefficients associated with object. It must be a vector with the same length of <code>coef(object)</code> and must be given in unconstrained form.                               |
| ...           | some methods for this generic require additional arguments. None are used in this method.  |

**Value**

a vector with the coefficients corresponding to object.

**SIDE EFFECTS**

On the left side of an assignment, sets the values of the coefficients of object to value.

|--------------|------------------------------------|
| coef.varFunc | <i>varFunc Object Coefficients</i> |
|--------------|------------------------------------|

---

Description

This method function extracts the coefficients associated with the variance function structure represented by object.

Usage

```
## S3 method for class 'varFunc'
coef(object, unconstrained, allCoef, ...)
## S3 replacement method for class 'varIdent'
coef(object, ...) <- value
```

Arguments

|               |  |
|---------------|--|
| object        | an object inheriting from class " <b>varFunc</b> " representing a variance function structure.   |
| unconstrained | a logical value. If TRUE the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If FALSE the coefficients are returned in "natural", generally constrained form. Defaults to TRUE.                               |
| allCoef       | a logical value. If FALSE only the coefficients which may vary during the optimization are returned. If TRUE all coefficients are returned. Defaults to FALSE.   |
| value         | a vector with the replacement values for the coefficients associated with object. It must be have the same length of coef{object} and must be given in unconstrained form. Object must be initialized before new values can be assigned to its coefficients. |
| ...           | some methods for this generic require additional arguments. None are used in this method.  |

Value

a vector with the coefficients corresponding to object.

SIDE EFFECTS

On the left side of an assignment, sets the values of the coefficients of object to value.

```

---

collapse.groupedData    *Collapse a groupedData Object*

---

## Description

If object has a single grouping factor, it is returned unchanged. Else, it is summarized by the values of the displayLevel grouping factor (or the combination of its values and the values of the covariate indicated in preserve, if any is present). The collapsed data is used to produce a new groupedData object, with grouping factor given by the displayLevel factor.

## Usage

```
## S3 method for class 'groupedData'
collapse(object, collapseLevel, displayLevel,
         outer, inner, preserve, FUN, subset, ...)
```

## Arguments

|               |   |
|---------------|---|
| object        | an object inheriting from class groupedData, generally with multiple grouping factors.  |
| collapseLevel | an optional positive integer or character string indicating the grouping level to use when collapsing the data. Level values increase from outermost to innermost grouping. Default is the highest or innermost level of grouping.  |
| displayLevel  | an optional positive integer or character string indicating the grouping level to use as the grouping factor for the collapsed data. Default is collapseLevel.  |
| outer         | an optional logical value or one-sided formula, indicating covariates that are outer to the displayLevel grouping factor. If equal to TRUE, the displayLevel element attr(object, "outer") is used to indicate the outer covariates. An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. Defaults to NULL, meaning that no outer covariates are to be used.                                       |
| inner         | an optional logical value or one-sided formula, indicating a covariate that is inner to the displayLevel grouping factor. If equal to TRUE, attr(object, "outer") is used to indicate the inner covariate. An inner covariate can change within the sets of rows defined by the grouping factor. Defaults to NULL, meaning that no inner covariate is present.  |
| preserve      | an optional one-sided formula indicating a covariate whose levels should be preserved when collapsing the data according to the collapseLevel grouping factor. The collapsing factor is obtained by pasting together the levels of the collapseLevel grouping factor and the values of the covariate to be preserved. Default is NULL, meaning that no covariates need to be preserved.   |
| FUN           | an optional summary function or a list of summary functions to be used for collapsing the data. The function or functions are applied only to variables in object that vary within the groups defined by collapseLevel. Invariant variables are always summarized by group using the unique value that they assume within that group. If FUN is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If FUN is a list of functions, the names in the list should designate classes of variables |

|        |   |
|--------|---|
|        | in the data such as ordered, factor, or numeric. The indicated function will be applied to any non-invariant variables of that class. The default functions to be used are mean for numeric factors, and Mode for both factor and ordered. The Mode function, defined internally in gsummary, returns the modal or most popular value of the variable. It is different from the mode function that returns the S-language mode of the variable. |
| subset | an optional named list. Names can be either positive integers representing grouping levels, or names of grouping factors. Each element in the list is a vector indicating the levels of the corresponding grouping factor to be preserved in the collapsed data. Default is NULL, meaning that all levels are used.   |
| ...    | some methods for this generic require additional arguments. None are used in this method.   |

Value

a groupedData object with a single grouping factor given by the displayLevel grouping factor, resulting from collapsing object over the levels of the collapseLevel grouping factor.

|-------------|-------------------------------|
| compareFits | <i>Compare Fitted Objects</i> |
|-------------|-------------------------------|

---

Description

The columns in object1 and object2 are put together in matrices which allow direct comparison of the individual elements for each object. Missing columns in either object are replaced by NAs.

Usage

```
compareFits(object1, object2, which)
```

Arguments

|                 |  |
|-----------------|--|
| object1,object2 | data frames, or matrices, with the same row names, but possibly different column names. These will usually correspond to coefficients from fitted objects with a grouping structure (e.g. lme and lmList objects). |
| which           | an optional integer or character vector indicating which columns in object1 and object2 are to be used in the returned object. Defaults to all columns.  |

Value

a three-dimensional array, with the third dimension given by the number of unique column names in either object1 or object2. To each column name there corresponds a matrix with as many rows as the rows in object1 and two columns, corresponding to object1 and object2. The returned object inherits from class compareFits.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

Examples

```
fm1 <- lmList(Orthodont)
fm2 <- lme(fm1)
compareFits(coef(fm1), coef(fm2))
```

---

|             |                            |
|-------------|----------------------------|
| comparePred | <i>Compare Predictions</i> |
|-------------|----------------------------|

---

Description

Predicted values are obtained at the specified values of primary for each object. If either object1 or object2 have a grouping structure (i.e. getGroups(object) is not NULL), predicted values are obtained for each group. When both objects determine groups, the group levels must be the same. If other covariates besides primary are used in the prediction model, their group-wise averages (numeric covariates) or most frequent values (categorical covariates) are used to obtain the predicted values. The original observations are also included in the returned object.

Usage

```
comparePred(object1, object2, primary, minimum, maximum,
            length.out, level, ...)
```

Arguments

- |                 |   |
|-----------------|---|
| object1,object2 | fitted model objects, from which predictions can be extracted using the predict method.   |
| primary         | an optional one-sided formula specifying the primary covariate to be used to generate the augmented predictions. By default, if a covariate can be extracted from the data used to generate the objects (using getCovariate), it will be used as primary. |
| minimum         | an optional lower limit for the primary covariate. Defaults to min(primary), after primary is evaluated in the data used in fitting object1.  |
| maximum         | an optional upper limit for the primary covariate. Defaults to max(primary), after primary is evaluated in the data used in fitting object1.  |

|            |  |
|------------|--|
| length.out | an optional integer with the number of primary covariate values at which to evaluate the predictions. Defaults to 51.  |
| level      | an optional integer specifying the desired prediction level. Levels increase from outermost to innermost grouping, with level 0 representing the population (fixed effects) predictions. Only one level can be specified. Defaults to the innermost level. |
| ...        | some methods for the generic may require additional arguments.   |

**Value**

a data frame with four columns representing, respectively, the values of the primary covariate, the groups (if object does not have a grouping structure, all elements will be 1), the predicted or observed values, and the type of value in the third column: the objects' names are used to classify the predicted values and original is used for the observed values. The returned object inherits from classes comparePred and augPred.

**Note**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: gls, lme, and lmList.

comparePred(fm1, fm2, length.out = 2)
```

---

|        |                                    |
|--------|------------------------------------|
| corAR1 | <i>AR(1) Correlation Structure</i> |
|--------|------------------------------------|

---

**Description**

This function is a constructor for the corAR1 class, representing an autocorrelation structure of order 1. Objects created using this constructor must later be initialized using the appropriate Initialize method.

**Usage**

```
corAR1(value, form, fixed)
```

**Arguments**

|       |  |
|-------|--|
| value | the value of the lag 1 autocorrelation, which must be between -1 and 1. Defaults to 0 (no autocorrelation).  |
| form  | a one sided formula of the form $\sim t$ , or $\sim t \mid g$ , specifying a time covariate $t$ and, optionally, a grouping factor $g$ . A covariate for this correlation structure must be integer valued. When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups. |
| fixed | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.  |

**Value**

an object of class `corAR1`, representing an autocorrelation structure of order 1.

**Description**

This function is a constructor for the corARMA class, representing an autocorrelation-moving average correlation structure of order (p, q). Objects created using this constructor must later be initialized using the appropriate Initialize method.

**Usage**

```
corARMA(value, form, p, q, fixed)
```

**Arguments**

|       |   |
|-------|---|
| value | a vector with the values of the autoregressive and moving average parameters, which must have length $p + q$ and all elements between -1 and 1. Defaults to a vector of zeros, corresponding to uncorrelated observations.  |
| form  | a one sided formula of the form $\sim t$ , or $\sim t   g$ , specifying a time covariate $t$ and, optionally, a grouping factor $g$ . A covariate for this correlation structure must be integer valued. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups. |
| p, q  | non-negative integers specifying respectively the autoregressive order and the moving average order of the ARMA structure. Both default to 0.   |
| fixed | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.   |

**Value**

an object of class corARMA, representing an autocorrelation-moving average correlation structure.

corCAR1

*Continuous AR(1) Correlation Structure***Description**

This function is a constructor for the `corCAR1` class, representing an autocorrelation structure of order 1, with a continuous time covariate. Objects created using this constructor must be later initialized using the appropriate `Initialize` method.

**Usage**

```
corCAR1(value, form, fixed)
```

**Arguments**

|                    |  |
|--------------------|--|
| <code>value</code> | the correlation between two observations one unit of time apart. Must be between 0 and 1. Defaults to 0.2.   |
| <code>form</code>  | a one sided formula of the form $\sim t$ , or $\sim t   g$ , specifying a time covariate $t$ and, optionally, a grouping factor $g$ . Covariates for this correlation structure need not be integer valued. When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups. |
| <code>fixed</code> | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to <code>FALSE</code> , in which case the coefficients are allowed to vary.  |

**Value**

an object of class `corCAR1`, representing an autocorrelation structure of order 1, with a continuous time covariate.

|------------|--------------------------------------|
| corClasses | <i>Correlation Structure Classes</i> |
|------------|--------------------------------------|

---

Description

Standard classes of correlation structures (corStruct) available in the nlme package.

Value

Available standard classes:

|             |  |
|-------------|--|
| corAR1      | autoregressive process of order 1.   |
| corARMA     | autoregressive moving average process, with arbitrary orders for the autoregressive and moving average components. |
| corCAR1     | continuous autoregressive process (AR(1) process for a continuous time covariate).                                 |
| corCompSymm | compound symmetry structure corresponding to a constant correlation.   |
| corExp      | exponential spatial correlation.   |
| corGaus     | Gaussian spatial correlation.  |
| corLin      | linear spatial correlation.  |
| corRatio    | Rational quadratics spatial correlation.   |
| corSpher    | spherical spatial correlation.   |
| corSymm     | general correlation matrix, with no additional structure.  |

Note

Users may define their own corStruct classes by specifying a constructor function and, at a minimum, methods for the functions corMatrix and coef. For examples of these functions, see the methods for classes corSymm and corAR1.

|             |  |
|-------------|--|
| corCompSymm | <i>Compound Symmetry Correlation Structure</i> |
|-------------|--|

---

Description

This function is a constructor for the `corCompSymm` class, representing a compound symmetry structure corresponding to uniform correlation. Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

Usage

```
corCompSymm(value, form, fixed)
```

Arguments

- |       |   |
|-------|---|
| value | the correlation between any two correlated observations. Defaults to 0.   |
| form  | a one sided formula of the form $\sim t$ , or $\sim t \mid g$ , specifying a time covariate $t$ and, optionally, a grouping factor $g$ . When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups. |
| fixed | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to <code>FALSE</code> , in which case the coefficients are allowed to vary.   |

Value

an object of class `corCompSymm`, representing a compound symmetry correlation structure.

## Examples

```
## covariate is observation order and grouping factor is Subject
cs1 <- corCompSymm(0.5, form = ~ 1 | Subject)

# Pinheiro and Bates, pp. 222-225
fm1BW.lme <- lme(weight ~ Time * Diet, BodyWeight,
  random = ~ Time)

# p. 223
fm2BW.lme <- update(fm1BW.lme, weights = varPower())

# p. 225
cs1CompSymm <- corCompSymm(value = 0.3, form = ~ 1 | Subject)
cs2CompSymm <- corCompSymm(value = 0.3, form = ~ age | Subject)
cs1CompSymm <- Initialize(cs1CompSymm, data = Orthodont)
corMatrix(cs1CompSymm)
```

corExp

*Exponential Correlation Structure*

## Description

This function is a constructor for the "corExp" class, representing an exponential spatial correlation structure. Letting  $d$  denote the range and  $n$  denote the nugget effect, the correlation between two observations a distance  $r$  apart is  $\exp(-r/d)$  when no nugget effect is present and  $(1 - n) \exp(-r/d)$  when a nugget effect is assumed. Objects created using this constructor must later be initialized using the appropriate Initialize method.

## Usage

```
corExp(value, form, nugget, metric, fixed)
```

## Arguments

|        |  |
|--------|--|
| value  | an optional vector with the parameter values in constrained form. If nugget is FALSE, value can have only one element, corresponding to the "range" of the exponential correlation structure, which must be greater than zero. If nugget is TRUE, meaning that a nugget effect is present, value can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to <code>numeric(0)</code> , which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized. |
| form   | a one sided formula of the form $\sim S1 + \dots + Sp$ , or $\sim S1 + \dots + Sp \mid g$ , specifying spatial covariates $S1$ through $Sp$ and, optionally, a grouping factor $g$ . When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups.  |
| nugget | an optional logical value indicating whether a nugget effect is present. Defaults to FALSE.  |

|        |  |
|--------|--|
| metric | an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean". |
| fixed  | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.  |

### Value

an object of class "corExp", also inheriting from class "corSpatial", representing an exponential spatial correlation structure.

  update(fm3BW.lme, correlation = corExp(form = ~ Time,
                                         nugget = TRUE))
anova(fm3BW.lme, fm4BW.lme)

```

corFactor

*Factor of a Correlation Matrix***Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all corStruct classes.

**Usage**

```
corFactor(object, ...)
```

**Arguments**

|        |  |
|--------|--|
| object | an object from which a correlation matrix can be extracted.          |
| ...    | some methods for this generic function require additional arguments. |

**Value**

will depend on the method function used; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[corFactor.corStruct](#), [recalc.corStruct](#)

**Examples**

```
## see the method function documentation
```

---

corFactor.corStruct     *Factor of a corStruct Object Matrix*

---

### Description

This method function extracts a transpose inverse square-root factor, or a series of transpose inverse square-root factors, of the correlation matrix, or list of correlation matrices, represented by object. Letting  $\Sigma$  denote a correlation matrix, a square-root factor of  $\Sigma$  is any square matrix  $L$  such that  $\Sigma = L'L$ . This method extracts  $L^{-t}$ .

### Usage

```
## S3 method for class 'corStruct'
corFactor(object, ...)
```

### Arguments

|        |   |
|--------|---|
| object | an object inheriting from class " <a href="#">corStruct</a> " representing a correlation structure, which must have been initialized (using <a href="#">Initialize</a> ). |
| ...    | some methods for this generic require additional arguments. None are used in this method.   |

### Value

If the correlation structure does not include a grouping factor, the returned value will be a vector with a transpose inverse square-root factor of the correlation matrix associated with object stacked column-wise. If the correlation structure includes a grouping factor, the returned value will be a vector with transpose inverse square-root factors of the correlation matrices for each group, stacked by group and stacked column-wise within each group.

### Note

This method function is used intensively in optimization algorithms and its value is returned as a vector for efficiency reasons. The [corMatrix](#) method function can be used to obtain transpose inverse square-root factors in matrix form.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

[corFactor](#), [corMatrix.corStruct](#), [recalc.corStruct](#), [Initialize.corStruct](#)

### Examples

```
cs1 <- corAR1(form = ~1 | Subject)
cs1 <- Initialize(cs1, data = Orthodont)
corFactor(cs1)
```

## Description

This function is a constructor for the `corGaus` class, representing a Gaussian spatial correlation structure. Letting  $d$  denote the range and  $n$  denote the nugget effect, the correlation between two observations a distance  $r$  apart is  $\exp(-(r/d)^2)$  when no nugget effect is present and  $(1-n)\exp(-(r/d)^2)$  when a nugget effect is assumed. Objects created using this constructor must later be initialized using the appropriate ‘Initialize method.

## Usage

```
corGaus(value, form, nugget, metric, fixed)
```

## Arguments

|        |   |
|--------|---|
| value  | an optional vector with the parameter values in constrained form. If <code>nugget</code> is <code>FALSE</code> , <code>value</code> can have only one element, corresponding to the "range" of the Gaussian correlation structure, which must be greater than zero. If <code>nugget</code> is <code>TRUE</code> , meaning that a nugget effect is present, <code>value</code> can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to <code>numeric(0)</code> , which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized. |
| form   | a one sided formula of the form $\sim S1 + \dots + Sp$ , or $\sim S1 + \dots + Sp \mid g$ , specifying spatial covariates $S1$ through $Sp$ and, optionally, a grouping factor $g$ . When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups.   |
| nugget | an optional logical value indicating whether a nugget effect is present. Defaults to <code>FALSE</code> .   |
| metric | an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".  |
| fixed  | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to <code>FALSE</code> , in which case the coefficients are allowed to vary.   |

## Value

an object of class `corGaus`, also inheriting from class `corSpatial`, representing a Gaussian spatial correlation structure.

fm1BW.lme <- lme(weight ~ Time * Diet, BodyWeight,
                random = ~ Time)

# p. 223
fm2BW.lme <- update(fm1BW.lme, weights = varPower())
# p 246
fm3BW.lme <- update(fm2BW.lme,
                  correlation = corExp(form = ~ Time))
# p. 249
fm8BW.lme <- update(fm3BW.lme, correlation = corGaus(form = ~ Time))
```

---

corLin

---

*Linear Correlation Structure*

---

**Description**

This function is a constructor for the corLin class, representing a linear spatial correlation structure. Letting  $d$  denote the range and  $n$  denote the nugget effect, the correlation between two observations a distance  $r < d$  apart is  $1 - (r/d)$  when no nugget effect is present and  $(1 - n)(1 - (r/d))$  when a nugget effect is assumed. If  $r \geq d$  the correlation is zero. Objects created using this constructor must later be initialized using the appropriate Initialize method.

**Usage**

```
corLin(value, form, nugget, metric, fixed)
```

**Arguments**

|        |   |
|--------|---|
| value  | an optional vector with the parameter values in constrained form. If nugget is FALSE, value can have only one element, corresponding to the "range" of the linear correlation structure, which must be greater than zero. If nugget is TRUE, meaning that a nugget effect is present, value can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to <code>numeric(0)</code> , which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized. |
| form   | a one sided formula of the form $\sim S1 + \dots + Sp$ , or $\sim S1 + \dots + Sp \mid g$ , specifying spatial covariates $S1$ through $Sp$ and, optionally, a grouping factor $g$ . When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups.   |
| nugget | an optional logical value indicating whether a nugget effect is present. Defaults to FALSE.   |
| metric | an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".  |
| fixed  | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.   |

**Value**

an object of class `corLin`, also inheriting from class `corSpatial`, representing a linear spatial correlation structure.

```

corMatrix

*Extract Correlation Matrix***Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all `corStruct` classes.

**Usage**

```
corMatrix(object, ...)
```

**Arguments**

|                     |  |
|---------------------|--|
| <code>object</code> | an object for which a correlation matrix can be extracted.           |
| <code>...</code>    | some methods for this generic function require additional arguments. |

**Value**

will depend on the method function used; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[corMatrix.corStruct](#), [corMatrix.pdMat](#)

**Examples**

```
## see the method function documentation
```

---

corMatrix.corStruct     *Matrix of a corStruct Object*

---

## Description

This method function extracts the correlation matrix (or its transpose inverse square-root factor), or list of correlation matrices (or their transpose inverse square-root factors) corresponding to covariate and object. Letting  $\Sigma$  denote a correlation matrix, a square-root factor of  $\Sigma$  is any square matrix  $L$  such that  $\Sigma = L'L$ . When `corr = FALSE`, this method extracts  $L^{-t}$ .

## Usage

```
## S3 method for class 'corStruct'
corMatrix(object, covariate, corr, ...)
```

## Arguments

|                        |  |
|------------------------|--|
| <code>object</code>    | an object inheriting from class " <code>corStruct</code> " representing a correlation structure.   |
| <code>covariate</code> | an optional covariate vector (matrix), or list of covariate vectors (matrices), at which values the correlation matrix, or list of correlation matrices, are to be evaluated. Defaults to <code>getCovariate(object)</code> .  |
| <code>corr</code>      | a logical value. If <code>TRUE</code> the function returns the correlation matrix, or list of correlation matrices, represented by <code>object</code> . If <code>FALSE</code> the function returns a transpose inverse square-root of the correlation matrix, or a list of transpose inverse square-root factors of the correlation matrices. |
| <code>...</code>       | some methods for this generic require additional arguments. None are used in this method.  |

## Value

If `covariate` is a vector (matrix), the returned value will be an array with the corresponding correlation matrix (or its transpose inverse square-root factor). If the `covariate` is a list of vectors (matrices), the returned value will be a list with the correlation matrices (or their transpose inverse square-root factors) corresponding to each component of `covariate`.

```

corNatural

*General correlation in natural parameterization***Description**

This function is a constructor for the `corNatural` class, representing a general correlation structure in the “natural” parameterization, which is described under [pdNatural](#). Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

**Usage**

```
corNatural(value, form, fixed)
```

**Arguments**

|                    |  |
|--------------------|--|
| <code>value</code> | an optional vector with the parameter values. Default is <code>numeric(0)</code> , which results in a vector of zeros of appropriate dimension being assigned to the parameters when object is initialized (corresponding to an identity correlation structure).   |
| <code>form</code>  | a one sided formula of the form $\sim t$ , or $\sim t \mid g$ , specifying a time covariate $t$ and, optionally, a grouping factor $g$ . A covariate for this correlation structure must be integer valued. When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups. |
| <code>fixed</code> | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to <code>FALSE</code> , in which case the coefficients are allowed to vary.  |

**Value**

an object of class `corNatural` representing a general correlation structure.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

**Examples**

```
## covariate is observation order and grouping factor is Subject
cs1 <- corNatural(form = ~ 1 | Subject)
```

corRatio

*Rational Quadratic Correlation Structure***Description**

This function is a constructor for the `corRatio` class, representing a rational quadratic spatial correlation structure. Letting  $d$  denote the range and  $n$  denote the nugget effect, the correlation between two observations a distance  $r$  apart is  $1/(1 + (r/d)^2)$  when no nugget effect is present and  $(1 - n)/(1 + (r/d)^2)$  when a nugget effect is assumed. Objects created using this constructor need to be later initialized using the appropriate `Initialize` method.

**Usage**

```
corRatio(value, form, nugget, metric, fixed)
```

**Arguments**

- |        |   |
|--------|---|
| value  | an optional vector with the parameter values in constrained form. If <code>nugget</code> is <code>FALSE</code> , <code>value</code> can have only one element, corresponding to the "range" of the rational quadratic correlation structure, which must be greater than zero. If <code>nugget</code> is <code>TRUE</code> , meaning that a nugget effect is present, <code>value</code> can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to <code>numeric(0)</code> , which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized. |
| form   | a one sided formula of the form $\sim S1 + \dots + Sp$ , or $\sim S1 + \dots + Sp \mid g$ , specifying spatial covariates $S1$ through $Sp$ and, optionally, a grouping factor $g$ . When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups.   |
| nugget | an optional logical value indicating whether a nugget effect is present. Defaults to <code>FALSE</code> .   |
| metric | an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".  |
| fixed  | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to <code>FALSE</code> , in which case the coefficients are allowed to vary.   |

**Value**

an object of class `corRatio`, also inheriting from class `corSpatial`, representing a rational quadratic spatial correlation structure.

                        nugget = TRUE))
```

---

corSpatial

*Spatial Correlation Structure*

---

**Description**

This function is a constructor for the `corSpatial` class, representing a spatial correlation structure. This class is "virtual", having four "real" classes, corresponding to specific spatial correlation structures, associated with it: `corExp`, `corGaus`, `corLin`, `corRatio`, and `corSpher`. The returned object will inherit from one of these "real" classes, determined by the `type` argument, and from the "virtual" `corSpatial` class. Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

**Usage**

```
corSpatial(value, form, nugget, type, metric, fixed)
```

**Arguments**

|        |  |
|--------|--|
| value  | an optional vector with the parameter values in constrained form. If nugget is FALSE, value can have only one element, corresponding to the "range" of the spatial correlation structure, which must be greater than zero. If nugget is TRUE, meaning that a nugget effect is present, value can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to <code>numeric(0)</code> , which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized. |
| form   | a one sided formula of the form $\sim S1 + \dots + Sp$ , or $\sim S1 + \dots + Sp \mid g$ , specifying spatial covariates $S1$ through $Sp$ and, optionally, a grouping factor $g$ . When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups.  |
| nugget | an optional logical value indicating whether a nugget effect is present. Defaults to FALSE.  |
| type   | an optional character string specifying the desired type of correlation structure. Available types include "spherical", "exponential", "gaussian", "linear", and "rational". See the documentation on the functions <code>corSpher</code> , <code>corExp</code> , <code>corGaus</code> , <code>corLin</code> , and <code>corRatio</code> for a description of these correlation structures. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "spherical".  |
| metric | an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".   |
| fixed  | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.  |

**Value**

an object of class determined by the type argument and also inheriting from class `corSpatial`, representing a spatial correlation structure.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

---

|          |  |
|----------|--|
| corSpher | <i>Spherical Correlation Structure</i> |
|----------|--|

---

Description

This function is a constructor for the `corSpher` class, representing a spherical spatial correlation structure. Letting  $d$  denote the range and  $n$  denote the nugget effect, the correlation between two observations a distance  $r < d$  apart is  $1 - 1.5(r/d) + 0.5(r/d)^3$  when no nugget effect is present and  $(1 - n)(1 - 1.5(r/d) + 0.5(r/d)^3)$  when a nugget effect is assumed. If  $r \geq d$  the correlation is zero. Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

Usage

```
corSpher(value, form, nugget, metric, fixed)
```

Arguments

|        |  |
|--------|--|
| value  | an optional vector with the parameter values in constrained form. If <code>nugget</code> is <code>FALSE</code> , <code>value</code> can have only one element, corresponding to the "range" of the spherical correlation structure, which must be greater than zero. If <code>nugget</code> is <code>TRUE</code> , meaning that a nugget effect is present, <code>value</code> can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to <code>numeric(0)</code> , which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized. |
| form   | a one sided formula of the form <code>~ S1+...+Sp</code> , or <code>~ S1+...+Sp   g</code> , specifying spatial covariates <code>S1</code> through <code>Sp</code> and, optionally, a grouping factor <code>g</code> . When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to <code>~ 1</code> , which corresponds to using the order of the observations in the data as a covariate, and no groups.  |
| nugget | an optional logical value indicating whether a nugget effect is present. Defaults to <code>FALSE</code> .  |

|        |  |
|--------|--|
| metric | an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean". |
| fixed  | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.  |

**Value**

an object of class `corSpher`, also inheriting from class `corSpatial`, representing a spherical spatial correlation structure.

```

corSymm

*General Correlation Structure***Description**

This function is a constructor for the `corSymm` class, representing a general correlation structure. The internal representation of this structure, in terms of unconstrained parameters, uses the spherical parametrization defined in Pinheiro and Bates (1996). Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

**Usage**

```
corSymm(value, form, fixed)
```

**Arguments**

- |       |   |
|-------|---|
| value | an optional vector with the parameter values. Default is <code>numeric(0)</code> , which results in a vector of zeros of appropriate dimension being assigned to the parameters when object is initialized (corresponding to an identity correlation structure).  |
| form  | a one sided formula of the form $\sim t$ , or $\sim t   g$ , specifying a time covariate $t$ and, optionally, a grouping factor $g$ . A covariate for this correlation structure must be integer valued. When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups. |
| fixed | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to <code>FALSE</code> , in which case the coefficients are allowed to vary.   |

**Value**

an object of class `corSymm` representing a general correlation structure.

Covariate

Assign Covariate Values

---

## Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all "[varFunc](#)" classes.

## Usage

```
covariate(object) <- value
```

## Arguments

|        |   |
|--------|---|
| object | any object with a covariate component.                          |
| value  | a value to be assigned to the covariate associated with object. |

## Value

will depend on the method function; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[getCovariate](#)

**Examples**

```
## see the method function documentation
```

---

|                   |                                 |
|-------------------|---------------------------------|
| Covariate.varFunc | <i>Assign varFunc Covariate</i> |
|-------------------|---------------------------------|

---

**Description**

The covariate(s) used in the calculation of the weights of the variance function represented by object is (are) replaced by value. If object has been initialized, value must have the same dimensions as `getCovariate(object)`.

**Usage**

```
## S3 replacement method for class 'varFunc'  
covariate(object) <- value
```

**Arguments**

|        |  |
|--------|--|
| object | an object inheriting from class " <a href="#">varFunc</a> ", representing a variance function structure. |
| value  | a value to be assigned to the covariate associated with object.  |

**Value**

a `varFunc` object similar to object, but with its `covariate` attribute replaced by value.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[getCovariate.varFunc](#)

**Examples**

```
vf1 <- varPower(1.1, form = ~age)  
covariate(vf1) <- Orthodont[["age"]]
```

|----------|------------------------|
| Dialyzer | High-Flux Hemodialyzer |
|----------|------------------------|

---

**Description**

The Dialyzer data frame has 140 rows and 5 columns.

**Format**

This data frame contains the following columns:

- Subject** an ordered factor with levels 10 < 8 < 2 < 6 < 3 < 5 < 9 < 7 < 1 < 4 < 17 < 20 < 11 < 12 < 16 < 13 < 14 < 18 < 15 < 19 giving the unique identifier for each subject
- QB** a factor with levels 200 and 300 giving the bovine blood flow rate (dL/min).
- pressure** a numeric vector giving the transmembrane pressure (dmHg).
- rate** the hemodialyzer ultrafiltration rate (mL/hr).
- index** index of observation within subject—1 through 7.

**Details**

Vonesh and Carter (1992) describe data measured on high-flux hemodialyzers to assess their *in vivo* ultrafiltration characteristics. The ultrafiltration rates (in mL/hr) of 20 high-flux dialyzers were measured at seven different transmembrane pressures (in dmHg). The *in vitro* evaluation of the dialyzers used bovine blood at flow rates of either 200~dl/min or 300~dl/min. The data, are also analyzed in Littell, Milliken, Stroup, and Wolfinger (1996).

Description

The Earthquake data frame has 182 rows and 5 columns.

Format

This data frame contains the following columns:

- Quake** an ordered factor with levels 20 < 16 < 14 < 10 < 3 < 8 < 23 < 22 < 6 < 13 < 7 < 21 < 18 < 15 < 4 < 12 < 19 < 5 < 9 < 1 < 2 < 17 < 11 indicating the earthquake on which the measurements were made.
- Richter** a numeric vector giving the intensity of the earthquake on the Richter scale.
- distance** the distance from the seismological measuring station to the epicenter of the earthquake (km).
- soil** a factor with levels 0 and 1 giving the soil condition at the measuring station, either soil or rock.
- accel** maximum horizontal acceleration observed (g).

Details

Measurements recorded at available seismometer locations for 23 large earthquakes in western North America between 1940 and 1980. They were originally given in Joyner and Boore (1981); are mentioned in Brillinger (1987); and are analyzed in Davidian and Giltinan (1995).

ergoStool

*Ergometrics experiment with stool types***Description**

The ergoStool data frame has 36 rows and 3 columns.

**Format**

This data frame contains the following columns:

**effort** a numeric vector giving the effort (Borg scale) required to arise from a stool.

**Type** a factor with levels T1, T2, T3, and T4 giving the stool type.

**Subject** an ordered factor giving a unique identifier for the subject in the experiment.

**Details**

Devore (2000) cites data from an article in *Ergometrics* (1993, pp. 519-535) on “The Effects of a Pneumatic Stool and a One-Legged Stool on Lower Limb Joint Load and Muscular Activity.”

Devore, J. L. (2000), *Probability and Statistics for Engineering and the Sciences (5th ed)*, Duxbury, Boston, MA.

**Examples**

```
fm1 <-
  lme(effort ~ Type, data = ergoStool, random = ~ 1 | Subject)
anova( fm1 )
```

Fatigue

*Cracks caused by metal fatigue***Description**

The Fatigue data frame has 262 rows and 3 columns.

**Format**

This data frame contains the following columns:

**Path** an ordered factor with levels 1 < 2 < 3 < 4 < 5 < 6 < 7 < 8 < 9 < 10 < 11 < 12 < 13 < 14 < 15 < 16 < 17 < 18 < 19 < 20 < 21 giving the test path (or test unit) number. The order is in terms of increasing failure time or decreasing terminal crack length.

**cycles** number of test cycles at which the measurement is made (millions of cycles).

**relLength** relative crack length (dimensionless).

## Details

These data are given in Lu and Meeker (1993) where they state “We obtained the data in Table 1 visually from figure 4.5.2 on page 242 of Bogdanoff and Kozin (1985).” The data represent the growth of cracks in metal for 21 test units. An initial notch of length 0.90 inches was made on each unit which then was subjected to several thousand test cycles. After every 10,000 test cycles the crack length was measured. Testing was stopped if the crack length exceeded 1.60 inches, defined as a failure, or at 120,000 cycles.

|        |                                  |
|--------|----------------------------------|
| fdHess | <i>Finite difference Hessian</i> |
|--------|----------------------------------|

---

## Description

Evaluate an approximate Hessian and gradient of a scalar function using finite differences.

## Usage

```
fdHess(pars, fun, ...,
      .relStep = .Machine$double.eps^(1/3), minAbsPar = 0)
```

## Arguments

|           |   |
|-----------|---|
| pars      | the numeric values of the parameters at which to evaluate the function fun and its derivatives.   |
| fun       | a function depending on the parameters pars that returns a numeric scalar.  |
| ...       | Optional additional arguments to fun  |
| .relStep  | The relative step size to use in the finite differences. It defaults to the cube root of .Machine\$double.eps   |
| minAbsPar | The minimum magnitude of a parameter value that is considered non-zero. It defaults to zero meaning that any non-zero value will be considered different from zero. |

## Details

This function uses a second-order response surface design known as a “Koschal design” to determine the parameter values at which the function is evaluated.

## Value

A list with components

|          |  |
|----------|--|
| mean     | the value of function fun evaluated at the parameter values pars |
| gradient | an approximate gradient (of length length(pars)).                |
| Hessian  | a matrix whose upper triangle contains an approximate Hessian.   |

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**Examples**

```
(fdH <- fdHess(c(12.3, 2.34), function(x) x[1]*(1-exp(-0.4*x[2]))))
stopifnot(length(fdH$ mean) == 1,
          length(fdH$ gradient) == 2,
          identical(dim(fdH$ Hessian), c(2L, 2L)))
```

---

fitted.glsStruct

---

*Calculate glsStruct Fitted Values*

---

**Description**

The fitted values for the linear model represented by object are extracted.

**Usage**

```
## S3 method for class 'glStruct'
fitted(object, glsFit, ...)
```

**Arguments**

|        |   |
|--------|---|
| object | an object inheriting from class " <a href="#">glStruct</a> ", representing a list of linear model components, such as <a href="#">corStruct</a> and " <a href="#">varFunc</a> " objects.  |
| glsFit | an optional list with components logLik (log-likelihood), beta (coefficients), sigma (standard deviation for error term), varBeta (coefficients' covariance matrix), fitted (fitted values), and residuals (residuals). Defaults to attr(object, "glsFit"). |
| ...    | some methods for this generic require additional arguments. None are used in this method.   |

**Value**

a vector with the fitted values for the linear model represented by object.

**Note**

This method function is generally only used inside gls and fitted.gls.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

|------------|----------------------------------|
| fitted.lme | <i>Extract lme Fitted Values</i> |
|------------|----------------------------------|

---

**Description**

The fitted values at level  $i$  are obtained by adding together the population fitted values (based only on the fixed effects estimates) and the estimated contributions of the random effects to the fitted values at grouping levels less or equal to  $i$ . The resulting values estimate the best linear unbiased predictions (BLUPs) at level  $i$ .

**Usage**

```
## S3 method for class 'lme'
fitted(object, level, asList, ...)
```

**Arguments**

|        |   |
|--------|---|
| object | an object inheriting from class " <a href="#">lme</a> ", representing a fitted linear mixed-effects model.  |
| level  | an optional integer vector giving the level(s) of grouping to be used in extracting the fitted values from object. Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping. |
| asList | an optional logical value. If TRUE and a single value is given in level, the returned object is a list with the fitted values split by groups; else the returned value is either a vector or a data frame, according to the length of level. Defaults to FALSE.                                       |
| ...    | some methods for this generic require additional arguments. None are used in this method.   |

**Value**

If a single level of grouping is specified in level, the returned value is either a list with the fitted values split by groups (`asList = TRUE`) or a vector with the fitted values (`asList = FALSE`); else, when multiple grouping levels are specified in level, the returned object is a data frame with columns given by the fitted values at different levels and the grouping factors. For a vector or data frame result the [napredict](#) method is applied.

```

---

fitted.lmeStruct

*Calculate lmeStruct Fitted Values*

---

**Description**

The fitted values at level  $i$  are obtained by adding together the population fitted values (based only on the fixed effects estimates) and the estimated contributions of the random effects to the fitted values at grouping levels less or equal to  $i$ . The resulting values estimate the best linear unbiased predictions (BLUPs) at level  $i$ .

Usage

```
## S3 method for class 'lmeStruct'  
fitted(object, level, conLin, lmeFit, ...)
```

Arguments

|        |   |
|--------|---|
| object | an object inheriting from class " <a href="#">lmeStruct</a> ", representing a list of linear mixed-effects model components, such as <code>reStruct</code> , <code>corStruct</code> , and <code>varFunc</code> objects.   |
| level  | an optional integer vector giving the level(s) of grouping to be used in extracting the fitted values from object. Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping. |
| conLin | an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying lme model. Defaults to <code>attr(object, "conLin")</code> .  |
| lmeFit | an optional list with components <code>beta</code> and <code>b</code> containing respectively the fixed effects estimates and the random effects estimates to be used to calculate the fitted values. Defaults to <code>attr(object, "lmeFit")</code> .   |
| ...    | some methods for this generic accept other optional arguments.  |

Value

if a single level of grouping is specified in `level`, the returned value is a vector with the fitted values at the desired level; else, when multiple grouping levels are specified in `level`, the returned object is a matrix with columns given by the fitted values at different levels.

Note

This method function is generally only used inside `lme` and `fitted.lme`.

|---------------|-------------------------------------|
| fitted.lmList | <i>Extract lmList Fitted Values</i> |
|---------------|-------------------------------------|

---

Description

The fitted values are extracted from each `lm` component of `object` and arranged into a list with as many components as `object`, or combined into a single vector.

Usage

```
## S3 method for class 'lmList'  
fitted(object, subset, asList, ...)
```

**Arguments**

|        |   |
|--------|---|
| object | an object inheriting from class " <a href="#">lmList</a> ", representing a list of <code>lm</code> objects with a common model.   |
| subset | an optional character or integer vector naming the <code>lm</code> components of object from which the fitted values are to be extracted. Default is <code>NULL</code> , in which case all components are used. |
| asList | an optional logical value. If <code>TRUE</code> , the returned object is a list with the fitted values split by groups; else the returned value is a vector. Defaults to <code>FALSE</code> .                   |
| ...    | some methods for this generic require additional arguments. None are used in this method.   |

**Value**

a list with components given by the fitted values of each `lm` component of object, or a vector with the fitted values for all `lm` components of object.

|-------------------|---|
| fitted.nlmeStruct | <i>Calculate nlmeStruct Fitted Values</i> |
|-------------------|---|

---

**Description**

The fitted values at level  $i$  are obtained by adding together the contributions from the estimated fixed effects and the estimated random effects at levels less or equal to  $i$  and evaluating the model function at the resulting estimated parameters. The resulting values estimate the predictions at level  $i$ .

**Usage**

```
## S3 method for class 'nlmeStruct'
fitted(object, level, conLin, ...)
```

**Arguments**

|        |   |
|--------|---|
| object | an object inheriting from class " <code>nlmeStruct</code> ", representing a list of mixed-effects model components, such as <code>reStruct</code> , <code>corStruct</code> , and <code>varFunc</code> objects, plus attributes specifying the underlying nonlinear model and the response variable.   |
| level  | an optional integer vector giving the level(s) of grouping to be used in extracting the fitted values from object. Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping.   |
| conLin | an optional condensed linear model object, consisting of a list with components " <code>Xy</code> ", corresponding to a regression matrix ( <i>X</i> ) combined with a response vector ( <i>y</i> ), and " <code>logLik</code> ", corresponding to the log-likelihood of the underlying nlme model. Defaults to <code>attr(object, "conLin")</code> . |
| ...    | additional arguments that could be given to this method. None are used.   |

**Value**

if a single level of grouping is specified in `level`, the returned value is a vector with the fitted values at the desired level; else, when multiple grouping levels are specified in `level`, the returned object is a matrix with columns given by the fitted values at different levels.

**Note**

This method function is generally only used inside `nlme` and `fitted.nlme`.

fixed.effects

*Extract Fixed Effects*

---

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `lmList` and `lme`.

**Usage**

```
fixed.effects(object, ...)
fixef(object, ...)
```

**Arguments**

object            any fitted model object from which fixed effects estimates can be extracted.  
 ...              some methods for this generic function require additional arguments.

**Value**

will depend on the method function used; see the appropriate documentation.

**References**

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

**See Also**

**Examples**

```
## see the method function documentation
```

---

fixef.lmList

---

*Extract lmList Fixed Effects*

---

**Description**

The average of the coefficients corresponding to the `lm` components of `object` is calculated.

**Usage**

```
## S3 method for class 'lmList'
fixef(object, ...)
```

**Arguments**

object            an object inheriting from class "[lmList](#)", representing a list of `lm` objects with a common model.  
 ...              some methods for this generic require additional arguments. None are used in this method.

**Value**

a vector with the average of the individual `lm` coefficients in `object`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[lmList](#), [random.effects.lmList](#)

**Examples**

```
fm1 <- lmList(distance ~ age | Subject, Orthodont)
fixed.effects(fm1)
```

|-------------------|----------------------------------|
| formula.pdBlocked | <i>Extract pdBlocked Formula</i> |
|-------------------|----------------------------------|

---

**Description**

The formula attributes of the pdMat elements of `x` are extracted and returned as a list, in case `asList=TRUE`, or converted to a single one-sided formula when `asList=FALSE`. If the pdMat elements do not have a formula attribute, a NULL value is returned.

**Usage**

```
## S3 method for class 'pdBlocked'
formula(x, asList, ...)
```

**Arguments**

|                     |  |
|---------------------|--|
| <code>x</code>      | an object inheriting from class "pdBlocked", representing a positive definite block diagonal matrix.   |
| <code>asList</code> | an optional logical value. If TRUE, a list with the formulas for the individual block diagonal elements of <code>x</code> is returned; else, if FALSE, a one-sided formula combining all individual formulas is returned. Defaults to FALSE. |
| <code>...</code>    | some methods for this generic require additional arguments. None are used in this method.  |

**Value**

a list of one-sided formulas, or a single one-sided formula, or NULL.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[pdBlocked](#), [pdMat](#)

**Examples**

```
pd1 <- pdBlocked(list(~ age, ~ Sex - 1))
formula(pd1)
formula(pd1, asList = TRUE)
```

---

|               |                              |
|---------------|------------------------------|
| formula.pdMat | <i>Extract pdMat Formula</i> |
|---------------|------------------------------|

---

### Description

This method function extracts the formula associated with a pdMat object, in which the column and row names are specified.

### Usage

```
## S3 method for class 'pdMat'  
formula(x, asList, ...)
```

### Arguments

|        |   |
|--------|---|
| x      | an object inheriting from class " <a href="#">pdMat</a> ", representing a positive definite matrix. |
| asList | logical. Should the asList argument be applied to each of the components? Never used.               |
| ...    | some methods for this generic require additional arguments. None are used in this method.           |

### Value

if x has a formula attribute, its value is returned, else NULL is returned.

### Note

Because factors may be present in formula(x), the pdMat object needs to have access to a data frame where the variables named in the formula can be evaluated, before it can resolve its row and column names from the formula.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

|------------------|--|
| formula.reStruct | <i>Extract reStruct Object Formula</i> |
|------------------|--|

---

**Description**

This method function extracts a formula from each of the components of `x`, returning a list of formulas.

**Usage**

```
## S3 method for class 'reStruct'
formula(x, asList, ...)
```

**Arguments**

|                     |  |
|---------------------|--|
| <code>x</code>      | an object inheriting from class " <code>reStruct</code> ", representing a random effects structure and consisting of a list of <code>pdMat</code> objects. |
| <code>asList</code> | logical. Should the <code>asList</code> argument be applied to each of the components?   |
| <code>...</code>    | some methods for this generic require additional arguments. None are used in this method.  |

**Value**

a list with the formulas of each component of `x`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

|--------|-----------------------------------|
| gapply | <i>Apply a Function by Groups</i> |
|--------|-----------------------------------|

---

**Description**

Applies the function to the distinct sets of rows of the data frame defined by groups.

**Usage**

```
gapply(object, which, FUN, form, level, groups, ...)
```

**Arguments**

|        |   |
|--------|---|
| object | an object to which the function will be applied - usually a groupedData object or a data.frame. Must inherit from class "data.frame".   |
| which  | an optional character or positive integer vector specifying which columns of object should be used with FUN. Defaults to all columns in object.   |
| FUN    | function to apply to the distinct sets of rows of the data frame object defined by the values of groups.  |
| form   | an optional one-sided formula that defines the groups. When this formula is given the right-hand side is evaluated in object, converted to a factor if necessary, and the unique levels are used to define the groups. Defaults to formula(object). |
| level  | an optional positive integer giving the level of grouping to be used in an object with multiple nested grouping levels. Defaults to the highest or innermost level of grouping.   |
| groups | an optional factor that will be used to split the rows into groups. Defaults to getGroups(object, form, level).   |
| ...    | optional additional arguments to the summary function FUN. Often it is helpful to specify na.rm = TRUE.   |

**Value**

Returns a data frame with as many rows as there are levels in the groups argument.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer, esp. sec. 3.4.

changeRecords <- gapply( Quinidine, FUN = function(frm)
  any(is.na(frm[["conc"]]) & is.na(frm[["dose"]])) ) )
```

Gasoline

*Refinery yield of gasoline***Description**

The Gasoline data frame has 32 rows and 6 columns.

**Format**

This data frame contains the following columns:

**yield** a numeric vector giving the percentage of crude oil converted to gasoline after distillation and fractionation

**endpoint** a numeric vector giving the temperature (degrees F) at which all the gasoline is vaporized

**Sample** an ordered factor giving the inferred crude oil sample number

**API** a numeric vector giving the crude oil gravity (degrees API)

**vapor** a numeric vector giving the vapor pressure of the crude oil (lbf/in<sup>2</sup>)

**ASTM** a numeric vector giving the crude oil 10% point ASTM—the temperature at which 10% of the crude oil has become vapor.

**Details**

Prater (1955) provides data on crude oil properties and gasoline yields. Atkinson (1985) uses these data to illustrate the use of diagnostics in multiple regression analysis. Three of the covariates—API, vapor, and ASTM—measure characteristics of the crude oil used to produce the gasoline. The other covariate — endpoint—is a characteristic of the refining process. Daniel and Wood (1980) notice that the covariates characterizing the crude oil occur in only ten distinct groups and conclude that the data represent responses measured on ten different crude oil samples.

getCovariate

*Extract Covariate from an Object***Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `corStruct`, `corSpatial`, `data.frame`, and `varFunc`.

**Usage**

```
getCovariate(object, form, data)
```

**Arguments**

|        |   |
|--------|---|
| object | any object with a covariate component   |
| form   | an optional one-sided formula specifying the covariate(s) to be extracted. Defaults to formula(object). |
| data   | a data frame in which to evaluate the variables defined in form.  |

**Value**

will depend on the method function used; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

```
getCovariate.corStruct
```

*Extract corStruct Object Covariate*

---

**Description**

This method function extracts the covariate(s) associated with object.

**Usage**

```
## S3 method for class 'corStruct'
getCovariate(object, form, data)
```

**Arguments**

|        |   |
|--------|---|
| object | an object inheriting from class corStruct representing a correlation structure.   |
| form   | this argument is included to make the method function compatible with the generic. It will be assigned the value of formula(object) and should not be modified. |
| data   | an optional data frame in which to evaluate the variables defined in form, in case object is not initialized and the covariate needs to be evaluated.           |

**Value**

when the correlation structure does not include a grouping factor, the returned value will be a vector or a matrix with the covariate(s) associated with `object`. If a grouping factor is present, the returned value will be a list of vectors or matrices with the covariate(s) corresponding to each grouping level.

cs1 <- corAR1(form = ~ 1 | Subject)
getCovariate(cs1, data = Orthodont)
```

---

```
getCovariate.data.frame
```

*Extract Data Frame Covariate*

---

**Description**

The right hand side of `form`, stripped of any conditioning expression (i.e. an expression following a `|` operator), is evaluated in `object`.

**Usage**

```
## S3 method for class 'data.frame'
getCovariate(object, form, data)
```

**Arguments**

|                     |  |
|---------------------|--|
| <code>object</code> | an object inheriting from class <code>data.frame</code> .  |
| <code>form</code>   | an optional formula specifying the covariate to be evaluated in <code>object</code> . Defaults to <code>formula(object)</code> . |
| <code>data</code>   | some methods for this generic require a separate data frame. Not used in this method.  |

**Value**

the value of the right hand side of `form`, stripped of any conditional expression, evaluated in `object`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**[getCovariateFormula](#)**Examples**

```
getCovariate(Orthodont)
```

---

```
getCovariate.varFunc
```

*Extract varFunc Covariate*

---

**Description**

This method function extracts the covariate(s) associated with the variance function represented by object, if any is present.

**Usage**

```
## S3 method for class 'varFunc'  
getCovariate(object, form, data)
```

**Arguments**

|        |  |
|--------|--|
| object | an object inheriting from class varFunc, representing a variance function structure.                 |
| form   | an optional formula specifying the covariate to be evaluated in object. Defaults to formula(object). |
| data   | some methods for this generic require a data object. Not used in this method.                        |

**Value**

if object has a covariate attribute, its value is returned; else NULL is returned.

**Author(s)**

|             |                                |
|-------------|--------------------------------|
| getData.gls | <i>Extract gls Object Data</i> |
|-------------|--------------------------------|

---

**Description**

If present in the calling sequence used to produce object, the data frame used to fit the model is obtained.

**Usage**

```
## S3 method for class 'gls'
getData(object)
```

**Arguments**

|        |  |
|--------|--|
| object | an object inheriting from class gls, representing a generalized least squares fitted linear model. |
|--------|--|

**Value**

if a data argument is present in the calling sequence that produced object, the corresponding data frame (with na.action and subset applied to it, if also present in the call that produced object) is returned; else, NULL is returned.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

**Examples**

```
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), data = Ovary,
           correlation = corAR1(form = ~ 1 | Mare))
getData(fm1)
```

---

getData.lme*Extract lme Object Data*

---

**Description**

If present in the calling sequence used to produce object, the data frame used to fit the model is obtained.

**Usage**

```
## S3 method for class 'lme'  
getData(object)
```

**Arguments**

object            an object inheriting from class lme, representing a linear mixed-effects fitted model.

**Value**

if a data argument is present in the calling sequence that produced object, the corresponding data frame (with na.action and subset applied to it, if also present in the call that produced object) is returned; else, NULL is returned.

Note that as from version 3.1-102, this only omits rows omitted in the fit if na.action = na.omit, and does not omit at all if na.action = na.exclude. That is generally what is wanted for plotting, the main use of this function.

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `corStruct`, `data.frame`, `gls`, `lme`, `lmList`, and `varFunc`.

**Usage**

```
getGroups(object, form, level, data, sep)
```

**Arguments**

|        |  |
|--------|--|
| object | any object   |
| form   | an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the   operator). Defaults to formula(object).  |
| level  | a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. This argument is optional for most methods of this generic function and defaults to all levels of nesting. |
| data   | a data frame in which to interpret the variables named in form. Optional for most methods.   |
| sep    | character, the separator to use between group levels when multiple levels are collapsed. The default is '/ '.  |

**Value**

will depend on the method function used; see the appropriate documentation.

getGroups.corStruct     *Extract corStruct Groups*

---

**Description**

This method function extracts the grouping factor associated with object, if any is present.

**Usage**

```
## S3 method for class 'corStruct'
getGroups(object, form, level, data, sep)
```

**Arguments**

|        |   |
|--------|---|
| object | an object inheriting from class corStruct representing a correlation structure.   |
| form   | this argument is included to make the method function compatible with the generic. It will be assigned the value of formula(object) and should not be modified. |
| level  | this argument is included to make the method function compatible with the generic and is not used.  |
| data   | an optional data frame in which to evaluate the variables defined in form, in case object is not initialized and the grouping factor needs to be evaluated.     |
| sep    | character, the separator to use between group levels when multiple levels are collapsed. The default is '/ '.   |

**Value**

if a grouping factor is present in the correlation structure represented by object, the function returns the corresponding factor vector; else the function returns NULL.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

**Examples**

```
cs1 <- corAR1(form = ~ 1 | Subject)
getGroups(cs1, data = Orthodont)
```

---

getGroups.data.frame    *Extract Groups from a Data Frame*

---

**Description**

Each variable named in the expression after the | operator on the right hand side of form is evaluated in object. If more than one variable is indicated in level they are combined into a data frame; else the selected variable is returned as a vector. When multiple grouping levels are defined in form and level > 1, the levels of the returned factor are obtained by pasting together the levels of the grouping factors of level greater or equal to level, to ensure their uniqueness.

**Usage**

```
## S3 method for class 'data.frame'
getGroups(object, form, level, data, sep)
```

**Arguments**

|        |  |
|--------|--|
| object | an object inheriting from class <code>data.frame</code> .  |
| form   | an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the <code> </code> operator). Defaults to <code>formula(object)</code> . |
| level  | a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. Defaults to all levels of nesting.                       |
| data   | unused   |
| sep    | character, the separator to use between group levels when multiple levels are collapsed. The default is <code>'/'</code> .   |

**Value**

either a data frame with columns given by the grouping factors indicated in `level`, from outer to inner, or, when a single level is requested, a factor representing the selected grouping factor.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

getGroups.gls

---

*Extract gls Object Groups*

---

**Description**

If present, the grouping factor associated to the correlation structure for the linear model represented by object is extracted.

**Usage**

```
## S3 method for class 'gls'
getGroups(object, form, level, data, sep)
```

**Arguments**

|        |  |
|--------|--|
| object | an object inheriting from class <code>gls</code> , representing a generalized least squares fitted linear model.   |
| form   | an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the <code> </code> operator). Defaults to <code>formula(object)</code> . Not used.   |
| level  | a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. This argument is optional for most methods of this generic function and defaults to all levels of nesting. Not used. |
| data   | a data frame in which to interpret the variables named in <code>form</code> . Optional for most methods. Not used.   |
| sep    | character, the separator to use between group levels when multiple levels are collapsed. The default is <code>'/'</code> . Not used.   |

**Value**

if the linear model represented by `object` incorporates a correlation structure and the corresponding `corStruct` object has a grouping factor, a vector with the group values is returned; else, `NULL` is returned.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

getGroups(fm1)
```

---

getGroups.lme

*Extract lme Object Groups*

---

**Description**

The grouping factors corresponding to the linear mixed-effects model represented by `object` are extracted. If more than one level is indicated in `level`, the corresponding grouping factors are combined into a data frame; else the selected grouping factor is returned as a vector.

**Usage**

```
## S3 method for class 'lme'
getGroups(object, form, level, data, sep)
```

**Arguments**

|        |   |
|--------|---|
| object | an object inheriting from class <code>lme</code> , representing a fitted linear mixed-effects model.  |
| form   | this argument is included to make the method function compatible with the generic and is ignored in this method.                                |
| level  | an optional integer vector giving the level(s) of grouping to be extracted from object. Defaults to the highest or innermost level of grouping. |
| data   | unused  |
| sep    | character, the separator to use between group levels when multiple levels are collapsed. The default is <code>'/'</code> .                      |

**Value**

either a data frame with columns given by the grouping factors indicated in `level`, or, when a single level is requested, a factor representing the selected grouping factor.

|------------------|-------------------------------------|
| getGroups.lmList | <i>Extract lmList Object Groups</i> |
|------------------|-------------------------------------|

---

**Description**

The grouping factor determining the partitioning of the observations used to produce the `lm` components of object is extracted.

**Usage**

```
## S3 method for class 'lmList'
getGroups(object, form, level, data, sep)
```

**Arguments**

|        |  |
|--------|--|
| object | an object inheriting from class <code>lmList</code> , representing a list of <code>lm</code> objects with a common model.  |
| form   | an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the <code> </code> operator). Defaults to <code>formula(object)</code> . Not used.   |
| level  | a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. This argument is optional for most methods of this generic function and defaults to all levels of nesting. Not used. |
| data   | a data frame in which to interpret the variables named in <code>form</code> . Optional for most methods. Not used.   |
| sep    | character, the separator to use between group levels when multiple levels are collapsed. The default is <code>'/'</code> . Not used.   |

**Value**

a vector with the grouping factor corresponding to the `lm` components of `object`.

|--------------------------------|-------------------------------|
| <code>getGroups.varFunc</code> | <i>Extract varFunc Groups</i> |
|--------------------------------|-------------------------------|

---

**Description**

This method function extracts the grouping factor associated with the variance function represented by `object`, if any is present.

**Usage**

```
## S3 method for class 'varFunc'
getGroups(object, form, level, data, sep)
```

**Arguments**

|        |  |
|--------|--|
| object | an object inheriting from class varFunc, representing a variance function structure.   |
| form   | an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the   operator). Defaults to formula(object). Not used.  |
| level  | a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. This argument is optional for most methods of this generic function and defaults to all levels of nesting. Not used. |
| data   | a data frame in which to interpret the variables named in form. Optional for most methods. Not used.   |
| sep    | character, the separator to use between group levels when multiple levels are collapsed. The default is '/'. Not used.   |

**Value**

if object has a groups attribute, its value is returned; else NULL is returned.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**Examples**

```
vf1 <- varPower(form = ~ age | Sex)
vf1 <- Initialize(vf1, Orthodont)
getGroups(vf1)
```

---

|                  |                                 |
|------------------|---------------------------------|
| getGroupsFormula | <i>Extract Grouping Formula</i> |
|------------------|---------------------------------|

---

**Description**

The conditioning expression associated with formula(object) (i.e. the expression after the | operator) is returned either as a named list of one-sided formulas, or a single one-sided formula, depending on the value of asList. The components of the returned list are ordered from outermost to innermost level and are named after the grouping factor expression.

**Usage**

```
getGroupsFormula(object, asList, sep)
```

**Arguments**

|        |   |
|--------|---|
| object | any object from which a formula can be extracted.   |
| asList | an optional logical value. If TRUE the returned value will be a list of formulas; else, if FALSE the returned value will be a one-sided formula. Defaults to FALSE. |
| sep    | character, the separator to use between group levels when multiple levels are collapsed. The default is '/'.  |

**Value**

a one-sided formula, or a list of one-sided formulas, with the grouping structure associated with `formula(object)`. If no conditioning expression is present in `formula(object)` a NULL value is returned.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

---

|           |   |
|-----------|---|
| getVarCov | <i>Extract variance-covariance matrix</i> |
|-----------|---|

---

**Description**

Extract the variance-covariance matrix from a fitted model, such as a mixed-effects model.

**Usage**

```
getVarCov(obj, ...)  
## S3 method for class 'lme'  
getVarCov(obj, individuals,  
  type = c("random.effects", "conditional", "marginal"), ...)  
## S3 method for class 'gls'  
getVarCov(obj, individual = 1, ...)
```

Arguments

|             |   |
|-------------|---|
| obj         | A fitted model. Methods are available for models fit by <a href="#">lme</a> and by <a href="#">gls</a>  |
| individuals | For models fit by <a href="#">lme</a> a vector of levels of the grouping factor can be specified for the conditional or marginal variance-covariance matrices.  |
| individual  | For models fit by <a href="#">gls</a> the only type of variance-covariance matrix provided is the marginal variance-covariance of the responses by group. The optional argument individual specifies the group of responses.  |
| type        | For models fit by <a href="#">lme</a> the type argument specifies the type of variance-covariance matrix, either "random.effects" for the random-effects variance-covariance (the default), or "conditional" for the conditional. variance-covariance of the responses or "marginal" for the the marginal variance-covariance of the responses. |
| ...         | Optional arguments for some methods, as described above   |

Value

A variance-covariance matrix or a list of variance-covariance matrices.

fm2 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary,
           correlation = corAR1(form = ~ 1 | Mare))
getVarCov(fm2)
```

---

|     |   |
|-----|---|
| gls | <i>Fit Linear Model Using Generalized Least Squares</i> |
|-----|---|

---

Description

This function fits a linear model using generalized least squares. The errors are allowed to be correlated and/or have unequal variances.

Usage

```
gls(model, data, correlation, weights, subset, method, na.action,
     control, verbose)
## S3 method for class 'gls'
update(object, model., ..., evaluate = TRUE)
```

**Arguments**

|             |   |
|-------------|---|
| object      | an object inheriting from class "gls", representing a generalized least squares fitted linear model.  |
| model       | a two-sided linear formula object describing the model, with the response on the left of a ~ operator and the terms, separated by + operators, on the right.  |
| model.      | Changes to the model – see <a href="#">update.formula</a> for details.  |
| data        | an optional data frame containing the variables named in model, correlation, weights, and subset. By default the variables are taken from the environment from which gls is called.   |
| correlation | an optional <a href="#">corStruct</a> object describing the within-group correlation structure. See the documentation of <a href="#">corClasses</a> for a description of the available corStruct classes. If a grouping variable is to be used, it must be specified in the form argument to the corStruct constructor. Defaults to NULL, corresponding to uncorrelated errors.   |
| weights     | an optional <a href="#">varFunc</a> object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to <a href="#">varFixed</a> , corresponding to fixed variance weights. See the documentation on <a href="#">varClasses</a> for a description of the available <a href="#">varFunc</a> classes. Defaults to NULL, corresponding to homoscedastic errors. |
| subset      | an optional expression indicating which subset of the rows of data should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.   |
| method      | a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "REML".  |
| na.action   | a function that indicates what should happen when the data contain NAs. The default action ( <a href="#">na.fail</a> ) causes gls to print an error message and terminate if there are any incomplete observations.   |
| control     | a list of control values for the estimation algorithm to replace the default values returned by the function <a href="#">glsControl</a> . Defaults to an empty list.  |
| verbose     | an optional logical value. If TRUE information on the evolution of the iterative algorithm is printed. Default is FALSE.  |
| ...         | some methods for this generic require additional arguments. None are used in this method.   |
| evaluate    | If TRUE evaluate the new call else return the call.   |

**Value**

an object of class "gls" representing the linear model fit. Generic functions such as `print`, `plot`, and `summary` have methods to show the results of the fit. See [glsObject](#) for the components of the fit. The functions [resid](#), [coef](#) and [fitted](#), can be used to extract some of its components.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## References

The different correlation structures available for the `correlation` argument are described in Box, G.E.P., Jenkins, G.M., and Reinsel G.C. (1994), Littell, R.C., Milliken, G.A., Stroup, W.W., and Wolfinger, R.D. (1996), and Venables, W.N. and Ripley, B.D. (2002). The use of variance functions for linear and nonlinear models is presented in detail in Carroll, R.J. and Ruppert, D. (1988) and Davidian, M. and Giltinan, D.M. (1995).

## Examples

```
# AR(1) errors within each Mare
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary,
          correlation = corAR1(form = ~ 1 | Mare))
# variance increases as a power of the absolute fitted values
fm2 <- update(fm1, weights = varPower())
```

---

`glsControl`

*Control Values for gls Fit*

---

## Description

The values supplied in the function call replace the defaults and a list with all possible arguments is returned. The returned list is used as the `control` argument to the `gls` function.

## Usage

```
glsControl(maxIter, msMaxIter, tolerance, msTol, msVerbose,
           singular.ok, returnObject, apVar, .relStep,
           opt=c("nlsminb", "optim"), optimMethod,
           minAbsParApVar, natural, sigma = NULL)
```

**Arguments**

|                |  |
|----------------|--|
| maxIter        | maximum number of iterations for the gls optimization algorithm. Default is 50.  |
| msMaxIter      | maximum number of iterations for the optimization step inside the gls optimization. Default is 50.   |
| tolerance      | tolerance for the convergence criterion in the gls algorithm. Default is 1e-6.   |
| msTol          | tolerance for the convergence criterion of the first outer iteration when optim is used. Default is 1e-7.  |
| msVerbose      | a logical value passed as the trace argument to ms (see documentation on that function). Default is FALSE.   |
| singular.ok    | a logical value indicating whether non-estimable coefficients (resulting from linear dependencies among the columns of the regression matrix) should be allowed. Default is FALSE. |
| returnObject   | a logical value indicating whether the fitted object should be returned when the maximum number of iterations is reached without convergence of the algorithm. Default is FALSE.   |
| apVar          | a logical value indicating whether the approximate covariance matrix of the variance-covariance parameters should be calculated. Default is TRUE.                                  |
| .relStep       | relative step for numerical derivatives calculations. Default is <code>.Machine\$double.eps^(1/3)</code> .   |
| opt            | the optimizer to be used, either <code>"nlminb"</code> (the current default) or <code>"optim"</code> (the previous default).   |
| optimMethod    | character - the optimization method to be used with the <code>optim</code> optimizer. The default is <code>"BFGS"</code> . An alternative is <code>"L-BFGS-B"</code> .             |
| minAbsParApVar | numeric value - minimum absolute parameter value in the approximate variance calculation. The default is <code>0.05</code> .   |
| natural        | logical. Should the natural parameterization be used for the approximate variance calculations? Default is TRUE.   |
| sigma          | optionally a positive number to fix the residual error at. If NULL, as by default, or 0, sigma is estimated.   |

**Value**

a list with components for each of the possible arguments.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>; the sigma option: Siem Heisterkamp and Bert van Willigen.

**See Also**

[gls](#)

**Examples**

```
# decrease the maximum number iterations in the optimization call and
# request that information on the evolution of the ms iterations be printed
glsControl(msMaxIter = 20, msVerbose = TRUE)
```

glsObject

*Fitted gls Object***Description**

An object returned by the [gls](#) function, inheriting from class "gls" and representing a generalized least squares fitted linear model. Objects of this class have methods for the generic functions `anova`, `coef`, `fitted`, `formula`, `getGroups`, `getResponse`, `intervals`, `logLik`, `plot`, `predict`, `print`, `residuals`, `summary`, and `update`.

**Value**

The following components must be included in a legitimate "gls" object.

|                           |   |
|---------------------------|---|
| <code>apVar</code>        | an approximate covariance matrix for the variance-covariance coefficients. If <code>apVar = FALSE</code> in the list of control values used in the call to <code>gls</code> , this component is equal to <code>NULL</code> .  |
| <code>call</code>         | a list containing an image of the <code>gls</code> call that produced the object.   |
| <code>coefficients</code> | a vector with the estimated linear model coefficients.  |
| <code>contrasts</code>    | a list with the contrasts used to represent factors in the model formula. This information is important for making predictions from a new data frame in which not all levels of the original factors are observed. If no factors are used in the model, this component will be an empty list. |
| <code>dims</code>         | a list with basic dimensions used in the model fit, including the components <code>N</code> - the number of observations in the data and <code>p</code> - the number of coefficients in the linear model.   |
| <code>fitted</code>       | a vector with the fitted values..   |
| <code>glsStruct</code>    | an object inheriting from class <code>glsStruct</code> , representing a list of linear model components, such as <code>corStruct</code> and <code>varFunc</code> objects.   |
| <code>groups</code>       | a vector with the correlation structure grouping factor, if any is present.   |
| <code>logLik</code>       | the log-likelihood at convergence.  |
| <code>method</code>       | the estimation method: either "ML" for maximum likelihood, or "REML" for restricted maximum likelihood.   |
| <code>numIter</code>      | the number of iterations used in the iterative algorithm.   |
| <code>residuals</code>    | a vector with the residuals.  |
| <code>sigma</code>        | the estimated residual standard error.  |
| <code>varBeta</code>      | an approximate covariance matrix of the coefficients estimates.   |

glsStruct

*Generalized Least Squares Structure***Description**

A generalized least squares structure is a list of model components representing different sets of parameters in the linear model. A glsStruct may contain corStruct and varFunc objects. NULL arguments are not included in the glsStruct list.

**Usage**

```
glsStruct(corStruct, varStruct)
```

**Arguments**

**corStruct** an optional corStruct object, representing a correlation structure. Default is NULL.

**varStruct** an optional varFunc object, representing a variance function structure. Default is NULL.

**Value**

a list of model variance-covariance components determining the parameters to be estimated for the associated linear model.

Glucose

*Glucose levels over time***Description**

The Glucose data frame has 378 rows and 4 columns.

**Format**

This data frame contains the following columns:

**Subject** an ordered factor with levels 6 < 2 < 3 < 5 < 1 < 4

**Time** a numeric vector

**conc** a numeric vector of glucose levels

**Meal** an ordered factor with levels 2am < 6am < 10am < 2pm < 6pm < 10pm

**Source**

Hand, D. and Crowder, M. (1996), *Practical Longitudinal Data Analysis*, Chapman and Hall, London.

---

Glucose2

*Glucose Levels Following Alcohol Ingestion*

---

**Description**

The Glucose2 data frame has 196 rows and 4 columns.

**Format**

This data frame contains the following columns:

**Subject** a factor with levels 1 to 7 identifying the subject whose glucose level is measured.

**Date** a factor with levels 1 2 indicating the occasion in which the experiment was conducted.

**Time** a numeric vector giving the time since alcohol ingestion (in min/10).

**glucose** a numeric vector giving the blood glucose level (in mg/dl).

**Details**

Hand and Crowder (Table A.14, pp. 180-181, 1996) describe data on the blood glucose levels measured at 14 time points over 5 hours for 7 volunteers who took alcohol at time 0. The same experiment was repeated on a second date with the same subjects but with a dietary additive used for all subjects.

gnls

*Fit Nonlinear Model Using Generalized Least Squares*

---

**Description**

This function fits a nonlinear model using generalized least squares. The errors are allowed to be correlated and/or have unequal variances.

**Usage**

```
gnls(model, data, params, start, correlation, weights, subset,
      na.action, naPattern, control, verbose)
```

**Arguments**

|                          |  |
|--------------------------|--|
| <code>model</code>       | a two-sided formula object describing the model, with the response on the left of a <code>~</code> operator and a nonlinear expression involving parameters and covariates on the right. If data is given, all names used in the formula should be defined as parameters or variables in the data frame.   |
| <code>data</code>        | an optional data frame containing the variables named in <code>model</code> , <code>correlation</code> , <code>weights</code> , <code>subset</code> , and <code>naPattern</code> . By default the variables are taken from the environment from which <code>gnls</code> is called.   |
| <code>params</code>      | an optional two-sided linear formula of the form $p_1 + \dots + p_n \sim x_1 + \dots + x_m$ , or list of two-sided formulas of the form $p_1 \sim x_1 + \dots + x_m$ , with possibly different models for each parameter. The $p_1, \dots, p_n$ represent parameters included on the right hand side of <code>model</code> and $x_1 + \dots + x_m$ define a linear model for the parameters (when the left hand side of the formula contains several parameters, they are all assumed to follow the same linear model described by the right hand side expression). A 1 on the right hand side of the formula(s) indicates a single fixed effects for the corresponding parameter(s). By default, the parameters are obtained from the names of <code>start</code> . |
| <code>start</code>       | an optional named list, or numeric vector, with the initial values for the parameters in <code>model</code> . It can be omitted when a <code>selfStarting</code> function is used in <code>model</code> , in which case the starting estimates will be obtained from a single call to the <code>nls</code> function.   |
| <code>correlation</code> | an optional <code>corStruct</code> object describing the within-group correlation structure. See the documentation of <code>corClasses</code> for a description of the available <code>corStruct</code> classes. If a grouping variable is to be used, it must be specified in the form argument to the <code>corStruct</code> constructor. Defaults to <code>NULL</code> , corresponding to uncorrelated errors.  |
| <code>weights</code>     | an optional <code>varFunc</code> object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to <code>varFixed</code> , corresponding to fixed variance weights. See the documentation on <code>varClasses</code> for a description of the available <code>varFunc</code> classes. Defaults to <code>NULL</code> , corresponding to homoscedastic errors.  |
| <code>subset</code>      | an optional expression indicating which subset of the rows of data should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.  |
| <code>na.action</code>   | a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>gnls</code> to print an error message and terminate if there are any incomplete observations.   |
| <code>naPattern</code>   | an expression or formula object, specifying which returned values are to be regarded as missing.   |
| <code>control</code>     | a list of control values for the estimation algorithm to replace the default values returned by the function <code>gnlsControl</code> . Defaults to an empty list.   |
| <code>verbose</code>     | an optional logical value. If <code>TRUE</code> information on the evolution of the iterative algorithm is printed. Default is <code>FALSE</code> .  |
| <code>...</code>         | some methods for this generic require additional arguments. None are used in this method.  |

**Value**

an object of class `gnls`, also inheriting from class `gls`, representing the nonlinear model fit. Generic functions such as `print`, `plot` and `summary` have methods to show the results of the fit. See `gnlsObject` for the components of the fit. The functions `resid`, `coef`, and `fitted` can be used to extract some of its components.

`gnlsControl`

*Control Values for gnls Fit*

---

**Description**

The values supplied in the function call replace the defaults and a list with all possible arguments is returned. The returned list is used as the `control` argument to the `gnls` function.

**Usage**

```
gnlsControl(maxIter, nlsMaxIter, msMaxIter, minScale, tolerance,
            nlsTol, msTol, returnObject, msVerbose,
            apVar, .relStep,
            opt = c("nlsminb", "optim"), optimMethod,
            minAbsParApVar, sigma = NULL)
```

**Arguments**

|                |  |
|----------------|--|
| maxIter        | maximum number of iterations for the gnls optimization algorithm. Default is 50.   |
| nlsMaxIter     | maximum number of iterations for the nls optimization step inside the gnls optimization. Default is 7.   |
| msMaxIter      | maximum number of iterations for the ms optimization step inside the gnls optimization. Default is 50.   |
| minScale       | minimum factor by which to shrink the default step size in an attempt to decrease the sum of squares in the nls step. Default 0.001.   |
| tolerance      | tolerance for the convergence criterion in the gnls algorithm. Default is 1e-6.  |
| nlsTol         | tolerance for the convergence criterion in nls step. Default is 1e-3.  |
| msTol          | tolerance for the convergence criterion of the first outer iteration when optim is used. Default is 1e-7.  |
| returnObject   | a logical value indicating whether the fitted object should be returned when the maximum number of iterations is reached without convergence of the algorithm. Default is FALSE. |
| msVerbose      | a logical value passed as the trace argument to ms (see documentation on that function). Default is FALSE.   |
| apVar          | a logical value indicating whether the approximate covariance matrix of the variance-covariance parameters should be calculated. Default is TRUE.                                |
| .relStep       | relative step for numerical derivatives calculations. Default is <code>.Machine\$double.eps^(1/3)</code> .   |
| opt            | the optimizer to be used, either <code>"nlsminb"</code> (the current default) or <code>"optim"</code> (the previous default).  |
| optimMethod    | character - the optimization method to be used with the <code>optim</code> optimizer. The default is <code>"BFGS"</code> . An alternative is <code>"L-BFGS-B"</code> .           |
| minAbsParApVar | numeric value - minimum absolute parameter value in the approximate variance calculation. The default is 0.05.   |
| sigma          | optionally a positive number to fix the residual error at. If NULL, as by default, or 0, sigma is estimated.   |

**Value**

a list with components for each of the possible arguments.

Description

An object returned by the `gnls` function, inheriting from class `gnls` and also from class `gls`, and representing a generalized nonlinear least squares fitted model. Objects of this class have methods for the generic functions `anova`, `coef`, `fitted`, `formula`, `getGroups`, `getResponse`, `intervals`, `logLik`, `plot`, `predict`, `print`, `residuals`, `summary`, and `update`.

Value

The following components must be included in a legitimate `gnls` object.

|                           |   |
|---------------------------|---|
| <code>apVar</code>        | an approximate covariance matrix for the variance-covariance coefficients. If <code>apVar = FALSE</code> in the control values used in the call to <code>gnls</code> , this component is equal to <code>NULL</code> .   |
| <code>call</code>         | a list containing an image of the <code>gnls</code> call that produced the object.  |
| <code>coefficients</code> | a vector with the estimated nonlinear model coefficients.   |
| <code>contrasts</code>    | a list with the contrasts used to represent factors in the model formula. This information is important for making predictions from a new data frame in which not all levels of the original factors are observed. If no factors are used in the model, this component will be an empty list. |
| <code>dims</code>         | a list with basic dimensions used in the model fit, including the components <code>N</code> - the number of observations used in the fit and <code>p</code> - the number of coefficients in the nonlinear model.  |
| <code>fitted</code>       | a vector with the fitted values.  |
| <code>modelStruct</code>  | an object inheriting from class <code>gnlsStruct</code> , representing a list of model components, such as <code>corStruct</code> and <code>varFunc</code> objects.   |
| <code>groups</code>       | a vector with the correlation structure grouping factor, if any is present.   |
| <code>logLik</code>       | the log-likelihood at convergence.  |
| <code>numIter</code>      | the number of iterations used in the iterative algorithm.   |
| <code>plist</code>        |   |
| <code>pmap</code>         |   |
| <code>residuals</code>    | a vector with the residuals.  |
| <code>sigma</code>        | the estimated residual standard error.  |
| <code>varBeta</code>      | an approximate covariance matrix of the coefficients estimates.   |

gnlsStruct

*Generalized Nonlinear Least Squares Structure*

---

**Description**

A generalized nonlinear least squares structure is a list of model components representing different sets of parameters in the nonlinear model. A `gnlsStruct` may contain `corStruct` and `varFunc` objects. NULL arguments are not included in the `gnlsStruct` list.

**Usage**

```
gnlsStruct(corStruct, varStruct)
```

**Arguments**

|                        |   |
|------------------------|---|
| <code>corStruct</code> | an optional <code>corStruct</code> object, representing a correlation structure. Default is NULL.     |
| <code>varStruct</code> | an optional <code>varFunc</code> object, representing a variance function structure. Default is NULL. |

**Value**

a list of model variance-covariance components determining the parameters to be estimated for the associated nonlinear model.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**Examples**

```
gnls1 <- gnlsStruct(corAR1(), varPower())
```

groupedData

*Construct a groupedData Object***Description**

An object of the groupedData class is constructed from the formula and data by attaching the formula as an attribute of the data, along with any of outer, inner, labels, and units that are given. If order.groups is TRUE the grouping factor is converted to an ordered factor with the ordering determined by FUN. Depending on the number of grouping levels and the type of primary covariate, the returned object will be of one of three classes: nfnGroupedData - numeric covariate, single level of nesting; nffGroupedData - factor covariate, single level of nesting; and nmGroupedData - multiple levels of nesting. Several modeling and plotting functions can use the formula stored with a groupedData object to construct default plots and models.

**Usage**

```
groupedData(formula, data, order.groups, FUN, outer, inner,
  labels, units)
## S3 method for class 'groupedData'
update(object, formula, data, order.groups, FUN,
  outer, inner, labels, units, ...)
```

**Arguments**

- |              |  |
|--------------|--|
| object       | an object inheriting from class groupedData.   |
| formula      | a formula of the form <code>resp ~ cov   group</code> where <code>resp</code> is the response, <code>cov</code> is the primary covariate, and <code>group</code> is the grouping factor. The expression <code>1</code> can be used for the primary covariate when there is no other suitable candidate. Multiple nested grouping factors can be listed separated by the <code>/</code> symbol as in <code>fact1/fact2</code> . In an expression like this the <code>fact2</code> factor is nested within the <code>fact1</code> factor.  |
| data         | a data frame in which the expressions in formula can be evaluated. The resulting groupedData object will consist of the same data values in the same order but with additional attributes.   |
| order.groups | an optional logical value, or list of logical values, indicating if the grouping factors should be converted to ordered factors according to the function FUN applied to the response from each group. If multiple levels of grouping are present, this argument can be either a single logical value (which will be repeated for all grouping levels) or a list of logical values. If no names are assigned to the list elements, they are assumed in the same order as the group levels (outermost to innermost grouping). Ordering within a level of grouping is done within the levels of the grouping factors which are outer to it. Changing the grouping factor to an ordered factor does not affect the ordering of the rows in the data frame but it does affect the order of the panels in a trellis display of the data or models fitted to the data. Defaults to TRUE. |
| FUN          | an optional summary function that will be applied to the values of the response for each level of the grouping factor, when <code>order.groups = TRUE</code> , to determine the ordering. Defaults to the max function.  |

|        |  |
|--------|--|
| outer  | an optional one-sided formula, or list of one-sided formulas, indicating covariates that are outer to the grouping factor(s). If multiple levels of grouping are present, this argument can be either a single one-sided formula, or a list of one-sided formulas. If no names are assigned to the list elements, they are assumed in the same order as the group levels (outermost to innermost grouping). An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. When plotting a groupedData object, the argument <code>outer = TRUE</code> causes the panels to be determined by the outer formula. The points within the panels are associated by level of the grouping factor. Defaults to <code>NULL</code> , meaning that no outer covariates are present. |
| inner  | an optional one-sided formula, or list of one-sided formulas, indicating covariates that are inner to the grouping factor(s). If multiple levels of grouping are present, this argument can be either a single one-sided formula, or a list of one-sided formulas. If no names are assigned to the list elements, they are assumed in the same order as the group levels (outermost to innermost grouping). An inner covariate can change within the sets of rows defined by the grouping factor. An inner formula can be used to associate points in a plot of a groupedData object. Defaults to <code>NULL</code> , meaning that no inner covariates are present.  |
| labels | an optional list of character strings giving labels for the response and the primary covariate. The label for the primary covariate is named <code>x</code> and that for the response is named <code>y</code> . Either label can be omitted.   |
| units  | an optional list of character strings giving the units for the response and the primary covariate. The units string for the primary covariate is named <code>x</code> and that for the response is named <code>y</code> . Either units string can be omitted.  |
| ...    | some methods for this generic require additional arguments. None are used in this method.  |

**Value**

an object of one of the classes `nfnGroupedData`, `nffGroupedData`, or `nmGroupedData`, and also inheriting from classes `groupedData` and `data.frame`.

## Examples

```
Orth.new <- # create a new copy of the groupedData object
groupedData( distance ~ age | Subject,
             data = as.data.frame( Orthodont ),
             FUN = mean,
             outer = ~ Sex,
             labels = list( x = "Age",
                           y = "Distance from pituitary to pterygomaxillary fissure" ),
             units = list( x = "(yr)", y = "(mm)" ) )

## Not run:
plot( Orth.new )          # trellis plot by Subject

## End(Not run)
formula( Orth.new )      # extractor for the formula
gsummary( Orth.new )     # apply summary by Subject
fm1 <- lme( Orth.new )   # fixed and groups formulae extracted from object
Orthodont2 <- update(Orthodont, FUN = mean)
```

---

gsummary

*Summarize by Groups*

---

## Description

Provide a summary of the variables in a data frame by groups of rows. This is most useful with a groupedData object to examine the variables by group.

## Usage

```
gsummary(object, FUN, omitGroupingFactor, form, level,
         groups, invariantsOnly, ...)
```

## Arguments

|                    |  |
|--------------------|--|
| object             | an object to be summarized - usually a groupedData object or a data.frame.   |
| FUN                | an optional summary function or a list of summary functions to be applied to each variable in the frame. The function or functions are applied only to variables in object that vary within the groups defined by groups. Invariant variables are always summarized by group using the unique value that they assume within that group. If FUN is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If FUN is a list of functions, the names in the list should designate classes of variables in the frame such as ordered, factor, or numeric. The indicated function will be applied to any non-invariant variables of that class. The default functions to be used are mean for numeric factors, and Mode for both factor and ordered. The Mode function, defined internally in gsummary, returns the modal or most popular value of the variable. It is different from the mode function that returns the S-language mode of the variable. |
| omitGroupingFactor | an optional logical value. When TRUE the grouping factor itself will be omitted from the group-wise summary but the levels of the grouping factor will continue to be used as the row names for the data frame that is produced by the summary. Defaults to FALSE.   |

|                |  |
|----------------|--|
| form           | an optional one-sided formula that defines the groups. When this formula is given, the right-hand side is evaluated in object, converted to a factor if necessary, and the unique levels are used to define the groups. Defaults to <code>formula(object)</code> .   |
| level          | an optional positive integer giving the level of grouping to be used in an object with multiple nested grouping levels. Defaults to the highest or innermost level of grouping.  |
| groups         | an optional factor that will be used to split the rows into groups. Defaults to <code>getGroups(object, form, level)</code> .  |
| invariantsOnly | an optional logical value. When TRUE only those covariates that are invariant within each group will be summarized. The summary value for the group is always the unique value taken on by that covariate within the group. The columns in the summary are of the same class as the corresponding columns in object. By definition, the grouping factor itself must be an invariant. When combined with <code>omitGroupingFactor = TRUE</code> , this option can be used to discover if there are invariant covariates in the data frame. Defaults to FALSE. |
| ...            | optional additional arguments to the summary functions that are invoked on the variables by group. Often it is helpful to specify <code>na.rm = TRUE</code> .  |

### Value

A `data.frame` with one row for each level of the grouping factor. The number of columns is at most the number of columns in object.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### References

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

|-----|--------------------------------------|
| Gun | <i>Methods for firing naval guns</i> |
|-----|--------------------------------------|

---

### Description

The Gun data frame has 36 rows and 4 columns.

### Format

This data frame contains the following columns:

**rounds** a numeric vector

**Method** a factor with levels M1 M2

**Team** an ordered factor with levels T1S < T3S < T2S < T1A < T2A < T3A < T1H < T3H < T2H

**Physique** an ordered factor with levels Slight < Average < Heavy

### Details

Hicks (p.180, 1993) reports data from an experiment on methods for firing naval guns. Gunners of three different physiques (slight, average, and heavy) tested two firing methods. Both methods were tested twice by each of nine teams of three gunners with identical physique. The response was the number of rounds fired per minute.

|     |  |
|-----|--|
| IGF | <i>Radioimmunoassay of IGF-I Protein</i> |
|-----|--|

---

### Description

The IGF data frame has 237 rows and 3 columns.

### Format

This data frame contains the following columns:

**Lot** an ordered factor giving the radioactive tracer lot.

**age** a numeric vector giving the age (in days) of the radioactive tracer.

**conc** a numeric vector giving the estimated concentration of IGF-I protein (ng/ml)

### Details

Davidian and Giltinan (1995) describe data obtained during quality control radioimmunoassays for ten different lots of radioactive tracer used to calibrate the Insulin-like Growth Factor (IGF-I) protein concentration measurements.

Initialize

Initialize Object

---

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `corStruct`, `lmeStruct`, `reStruct`, and `varFunc`.

**Usage**

```
Initialize(object, data, ...)
```

**Arguments**

|                     |   |
|---------------------|---|
| <code>object</code> | any object requiring initialization, e.g. "plug-in" structures such as <code>corStruct</code> and <code>varFunc</code> objects. |
| <code>data</code>   | a data frame to be used in the initialization procedure.  |
| <code>...</code>    | some methods for this generic function require additional arguments.  |

**Value**

an initialized object with the same class as `object`. Changes introduced by the initialization procedure will depend on the method function used; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

**See Also**

[Initialize.varFunc](#), [isInitialized](#)

**Examples**

```
## see the method function documentation
```

---

Initialize.corStruct    *Initialize corStruct Object*

---

## Description

This method initializes object by evaluating its associated covariate(s) and grouping factor, if any is present, in data, calculating various dimensions and constants used by optimization algorithms involving corStruct objects (see the appropriate Dim method documentation), and assigning initial values for the coefficients in object, if none were present.

## Usage

```
## S3 method for class 'corStruct'
Initialize(object, data, ...)
```

## Arguments

|        |   |
|--------|---|
| object | an object inheriting from class " <a href="#">corStruct</a> " representing a correlation structure. |
| data   | a data frame in which to evaluate the variables defined in formula(object).                         |
| ...    | this argument is included to make this method compatible with the generic.                          |

## Value

an initialized object with the same class as object representing a correlation structure.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## References

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

## Examples

```
cs1 <- corAR1(form = ~ 1 | Subject)
cs1 <- Initialize(cs1, data = Orthodont)
```

---

Initialize.glsStruct    *Initialize a glsStruct Object*

---

**Description**

The individual linear model components of the glsStruct list are initialized.

**Usage**

```
## S3 method for class 'glsStruct'
Initialize(object, data, control, ...)
```

**Arguments**

|         |   |
|---------|---|
| object  | an object inheriting from class " <a href="#">glsStruct</a> ", representing a list of linear model components, such as corStruct and varFunc objects.   |
| data    | a data frame in which to evaluate the variables defined in formula(object).   |
| control | an optional list with control parameters for the initialization and optimization algorithms used in gls. Defaults to list(singular.ok = FALSE), implying that linear dependencies are not allowed in the model. |
| ...     | some methods for this generic require additional arguments. None are used in this method.   |

**Value**

a glsStruct object similar to object, but with initialized model components.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[gls](#), [Initialize.corStruct](#), [Initialize.varFunc](#), [Initialize](#)

---

Initialize.lmeStruct    *Initialize an lmeStruct Object*

---

**Description**

The individual linear mixed-effects model components of the lmeStruct list are initialized.

**Usage**

```
## S3 method for class 'lmeStruct'
Initialize(object, data, groups, conLin, control, ...)
```

**Arguments**

|         |   |
|---------|---|
| object  | an object inheriting from class " <a href="#">lmeStruct</a> ", representing a list of linear mixed-effects model components, such as <a href="#">reStruct</a> , <a href="#">corStruct</a> , and <a href="#">varFunc</a> objects.  |
| data    | a data frame in which to evaluate the variables defined in <code>formula(object)</code> .   |
| groups  | a data frame with the grouping factors corresponding to the lme model associated with object as columns, sorted from innermost to outermost grouping level.   |
| conLin  | an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying lme model. Defaults to <code>attr(object, "conLin")</code> .  |
| control | an optional list with control parameters for the initialization and optimization algorithms used in lme. Defaults to <code>list(niterEM=20, gradHess=TRUE)</code> , implying that 20 EM iterations are to be used in the derivation of initial estimates for the coefficients of the <a href="#">reStruct</a> component of object and, if possible, numerical gradient vectors and Hessian matrices for the log-likelihood function are to be used in the optimization algorithm. |
| ...     | some methods for this generic require additional arguments. None are used in this method.   |

**Value**

an [lmeStruct](#) object similar to object, but with initialized model components.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[lme](#), [Initialize.reStruct](#), [Initialize.corStruct](#), [Initialize.varFunc](#), [Initialize](#)

---

`Initialize.reStruct`     *Initialize reStruct Object*

---

**Description**

Initial estimates for the parameters in the `pdMat` objects forming object, which have not yet been initialized, are obtained using the methodology described in Bates and Pinheiro (1998). These estimates may be refined using a series of EM iterations, as described in Bates and Pinheiro (1998). The number of EM iterations to be used is defined in `control`.

**Usage**

```
## S3 method for class 'reStruct'
Initialize(object, data, conLin, control, ...)
```

**Arguments**

|         |   |
|---------|---|
| object  | an object inheriting from class " <a href="#">reStruct</a> ", representing a random effects structure and consisting of a list of pdMat objects.  |
| data    | a data frame in which to evaluate the variables defined in formula(object).   |
| conLin  | a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model.                          |
| control | an optional list with a single component niterEM controlling the number of iterations for the EM algorithm used to refine initial parameter estimates. It is given as a list for compatibility with other Initialize methods. Defaults to list(niterEM = 20). |
| ...     | some methods for this generic require additional arguments. None are used in this method.   |

**Value**

an reStruct object similar to object, but with all pdMat components initialized.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[reStruct](#), [pdMat](#), [Initialize](#)

---

|                    |                                  |
|--------------------|----------------------------------|
| Initialize.varFunc | <i>Initialize varFunc Object</i> |
|--------------------|----------------------------------|

---

**Description**

This method initializes object by evaluating its associated covariate(s) and grouping factor, if any is present, in data; determining if the covariate(s) need to be updated when the values of the coefficients associated with object change; initializing the log-likelihood and the weights associated with object; and assigning initial values for the coefficients in object, if none were present. The covariate(s) will only be initialized if no update is needed when coef(object) changes.

**Usage**

```
## S3 method for class 'varFunc'
Initialize(object, data, ...)
```

**Arguments**

|        |  |
|--------|--|
| object | an object inheriting from class " <a href="#">varFunc</a> ", representing a variance function structure. |
| data   | a data frame in which to evaluate the variables named in formula(object).                                |
| ...    | this argument is included to make this method compatible with the generic.                               |

**Value**

an initialized object with the same class as object representing a variance function structure.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[Initialize](#)

**Examples**

```
vf1 <- varPower( form = ~ age | Sex )
vf1 <- Initialize( vf1, Orthodont )
```

---

intervals

---

*Confidence Intervals on Coefficients*

---

**Description**

Confidence intervals on the parameters associated with the model represented by object are obtained. This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `gls`, `lme`, and `lmList`.

**Usage**

```
intervals(object, level, ...)
```

**Arguments**

|        |  |
|--------|--|
| object | a fitted model object from which parameter estimates can be extracted.         |
| level  | an optional numeric value for the interval confidence level. Defaults to 0.95. |
| ...    | some methods for the generic may require additional arguments.                 |

**Value**

will depend on the method function used; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

**See Also**

[intervals.lme](#), [intervals.lmList](#), [intervals.gls](#)

**Examples**

```
## see the method documentation
```

**Description**

Approximate confidence intervals for the parameters in the linear model represented by object are obtained, using a normal approximation to the distribution of the (restricted) maximum likelihood estimators (the estimators are assumed to have a normal distribution centered at the true parameter values and with covariance matrix equal to the negative inverse Hessian matrix of the (restricted) log-likelihood evaluated at the estimated parameters). Confidence intervals are obtained in an unconstrained scale first, using the normal approximation, and, if necessary, transformed to the constrained scale.

**Usage**

```
## S3 method for class 'gls'
intervals(object, level, which, ...)
```

**Arguments**

|        |  |
|--------|--|
| object | an object inheriting from class "gls", representing a generalized least squares fitted linear model.   |
| level  | an optional numeric value for the interval confidence level. Defaults to 0.95.   |
| which  | an optional character string specifying the subset of parameters for which to construct the confidence intervals. Possible values are "all" for all parameters, "var-cov" for the variance-covariance parameters only, and "coef" for the linear model coefficients only. Defaults to "all". |
| ...    | some methods for this generic require additional arguments. None are used in this method.  |

**Value**

a list with components given by data frames with rows corresponding to parameters and columns lower, est., and upper representing respectively lower confidence limits, the estimated values, and upper confidence limits for the parameters. Possible components are:

|           |   |
|-----------|---|
| coef      | linear model coefficients, only present when which is not equal to "var-cov".   |
| corStruct | correlation parameters, only present when which is not equal to "coef" and a correlation structure is used in object.             |
| varFunc   | variance function parameters, only present when which is not equal to "coef" and a variance function structure is used in object. |
| sigma     | residual standard error.  |

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

Examples

```
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary,
           correlation = corAR1(form = ~ 1 | Mare))
intervals(fm1)
```

---

|               |   |
|---------------|---|
| intervals.lme | <i>Confidence Intervals on lme Parameters</i> |
|---------------|---|

---

Description

Approximate confidence intervals for the parameters in the linear mixed-effects model represented by object are obtained, using a normal approximation to the distribution of the (restricted) maximum likelihood estimators (the estimators are assumed to have a normal distribution centered at the true parameter values and with covariance matrix equal to the negative inverse Hessian matrix of the (restricted) log-likelihood evaluated at the estimated parameters). Confidence intervals are obtained in an unconstrained scale first, using the normal approximation, and, if necessary, transformed to the constrained scale. The pdNatural parametrization is used for general positive-definite matrices.

Usage

```
## S3 method for class 'lme'
intervals(object, level = 0.95,
          which = c("all", "var-cov", "fixed"), ...)
```

Arguments

|        |   |
|--------|---|
| object | an object inheriting from class " <a href="#">lme</a> ", representing a fitted linear mixed-effects model.  |
| level  | an optional numeric value with the confidence level for the intervals. Defaults to 0.95.  |
| which  | an optional character string specifying the subset of parameters for which to construct the confidence intervals. Possible values are "all" for all parameters, "var-cov" for the variance-covariance parameters only, and "fixed" for the fixed effects only. Defaults to "all". |
| ...    | some methods for this generic require additional arguments. None are used in this method.   |

Value

a list with components given by data frames with rows corresponding to parameters and columns lower, est., and upper representing respectively lower confidence limits, the estimated values, and upper confidence limits for the parameters. Possible components are:

|          |   |
|----------|---|
| fixed    | fixed effects, only present when which is not equal to "var-cov".                               |
| reStruct | random effects variance-covariance parameters, only present when which is not equal to "fixed". |

|           |   |
|-----------|---|
| corStruct | within-group correlation parameters, only present when which is not equal to "fixed" and a correlation structure is used in object.             |
| varFunc   | within-group variance function parameters, only present when which is not equal to "fixed" and a variance function structure is used in object. |
| sigma     | within-group standard deviation.  |

Examples

```
fm1 <- lme(distance ~ age, Orthodont, random = ~ age | Subject)
intervals(fm1)
```

---

|                  |  |
|------------------|--|
| intervals.lmList | <i>Confidence Intervals on lmList Coefficients</i> |
|------------------|--|

---

Description

Confidence intervals on the linear model coefficients are obtained for each `lm` component of object and organized into a three dimensional array. The first dimension corresponding to the names of the object components. The second dimension is given by `lower`, `est.`, and `upper` corresponding, respectively, to the lower confidence limit, estimated coefficient, and upper confidence limit. The third dimension is given by the coefficients names.

Usage

```
## S3 method for class 'lmList'
intervals(object, level = 0.95, pool = attr(object, "pool"), ...)
```

Arguments

|        |  |
|--------|--|
| object | an object inheriting from class " <a href="#">lmList</a> ", representing a list of <code>lm</code> objects with a common model.                              |
| level  | an optional numeric value with the confidence level for the intervals. Defaults to 0.95.   |
| pool   | an optional logical value indicating whether a pooled estimate of the residual standard error should be used. Default is <code>attr(object, "pool")</code> . |
| ...    | some methods for this generic require additional arguments. None are used in this method.  |

Value

a three dimensional array with the confidence intervals and estimates for the coefficients of each lm component of object.

|------------|-----------------------------------|
| isBalanced | <i>Check a Design for Balance</i> |
|------------|-----------------------------------|

---

Description

Check the design of the experiment or study for balance.

Usage

```
isBalanced(object, countOnly, level)
```

Arguments

|           |   |
|-----------|---|
| object    | A groupedData object containing a data frame and a formula that describes the roles of variables in the data frame. The object will have one or more nested grouping factors and a primary covariate.                             |
| countOnly | A logical value indicating if the check for balance should only consider the number of observations at each level of the grouping factor(s). Defaults to FALSE.   |
| level     | an optional integer vector specifying the desired prediction levels. Levels increase from outermost to innermost grouping, with level 0 representing the population (fixed effects) predictions. Defaults to the innermost level. |

Details

A design is balanced with respect to the grouping factor(s) if there are the same number of observations at each distinct value of the grouping factor or each combination of distinct levels of the nested grouping factors. If countOnly is FALSE the design is also checked for balance with respect to the primary covariate, which is often the time of the observation. A design is balanced with respect to the grouping factor and the covariate if the number of observations at each distinct level (or combination of levels for nested factors) is constant and the times at which the observations are taken (in general, the values of the primary covariates) also are constant.

**Value**

TRUE or FALSE according to whether the data are balanced or not

**Examples**

```
pd1 <- pdDiag(~age)
isInitialized(pd1)
```

---

LDEsysMat

*Generate system matrix for LDEs*

---

## Description

Generate the system matrix for the linear differential equations determined by a compartment model.

## Usage

```
LDEsysMat(pars, incidence)
```

## Arguments

|                        |  |
|------------------------|--|
| <code>pars</code>      | a numeric vector of parameter values.  |
| <code>incidence</code> | an integer matrix with columns named From, To, and Par. Values in the Par column must be in the range 1 to <code>length(pars)</code> . Values in the From column must be between 1 and the number of compartments. Values in the To column must be between 0 and the number of compartments. |

## Details

A compartment model describes material transfer between  $k$  in a system of  $k$  compartments to a linear system of differential equations. Given a description of the system and a vector of parameter values this function returns the system matrix.

This function is intended for use in a general system for solving compartment models, as described in Bates and Watts (1988).

## Value

A  $k$  by  $k$  numeric matrix.

## Author(s)

Douglas Bates <bates@stat.wisc.edu>

## References

Bates, D. M. and Watts, D. G. (1988), *Nonlinear Regression Analysis and Its Applications*, Wiley, New York.

## Examples

```
# incidence matrix for a two compartment open system
incidence <-
  matrix(c(1,1,2,2,2,1,3,2,0), ncol = 3, byrow = TRUE,
    dimnames = list(NULL, c("Par", "From", "To")))
incidence
LDEsysMat(c(1.2, 0.3, 0.4), incidence)
```

lme

*Linear Mixed-Effects Models***Description**

This generic function fits a linear mixed-effects model in the formulation described in Laird and Ware (1982) but allowing for nested random effects. The within-group errors are allowed to be correlated and/or have unequal variances.

The methods [lme.lmList](#) and [lme.groupedData](#) are documented separately.

**Usage**

```
lme(fixed, data, random, correlation, weights, subset, method,
    na.action, control, contrasts = NULL, keep.data = TRUE)
```

```
## S3 method for class 'lme'
update(object, fixed., ..., evaluate = TRUE)
```

**Arguments**

- |        |   |
|--------|---|
| object | an object inheriting from class <code>lme</code> , representing a fitted linear mixed-effects model.  |
| fixed  | a two-sided linear formula object describing the fixed-effects part of the model, with the response on the left of a <code>~</code> operator and the terms, separated by <code>+</code> operators, on the right, an <code>"lmList"</code> object, or a <code>"groupedData"</code> object.<br>There is limited support for formulae such as <code>resp ~ 1</code> and <code>resp ~ 0</code> , and less prior to version '3.1-112'.   |
| fixed. | Changes to the fixed-effects formula – see <a href="#">update.formula</a> for details.  |
| data   | an optional data frame containing the variables named in <code>fixed</code> , <code>random</code> , <code>correlation</code> , <code>weights</code> , and <code>subset</code> . By default the variables are taken from the environment from which <code>lme</code> is called.  |
| random | optionally, any of the following: (i) a one-sided formula of the form <code>~ x1 + ... + xn   g1/.../gm</code> , with <code>x1 + ... + xn</code> specifying the model for the random effects and <code>g1/.../gm</code> the grouping structure ( <code>m</code> may be equal to 1, in which case no <code>/</code> is required). The random effects formula will be repeated for all levels of grouping, in the case of multiple levels of grouping; (ii) a list of one-sided formulas of the form <code>~ x1 + ... + xn   g</code> , with possibly different random effects models for each grouping level. The order of nesting will be assumed the same as the order of the elements in the list; (iii) a one-sided formula of the form <code>~ x1 + ... + xn</code> , or a <code>pdMat</code> object with a formula (i.e. a non-NULL value for <code>formula(object)</code> ), or a list of such formulas or <code>pdMat</code> objects. In this case, the grouping structure formula will be derived from the data used to fit the linear mixed-effects model, which should inherit from class <code>"groupedData"</code> ; (iv) a named list of formulas or <code>pdMat</code> objects as in (iii), with the grouping factors as names. The order of nesting will be assumed the same as the order of the elements in the list; (v) an <code>reStruct</code> object. See the documentation on <code>pdClasses</code> for a description of the available <code>pdMat</code> classes. Defaults to a formula consisting of the right hand side of <code>fixed</code> . |

|             |  |
|-------------|--|
| correlation | an optional <code>corStruct</code> object describing the within-group correlation structure. See the documentation of <code>corClasses</code> for a description of the available <code>corStruct</code> classes. Defaults to <code>NULL</code> , corresponding to no within-group correlations.  |
| weights     | an optional <code>varFunc</code> object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to <code>varFixed</code> , corresponding to fixed variance weights. See the documentation on <code>varClasses</code> for a description of the available <code>varFunc</code> classes. Defaults to <code>NULL</code> , corresponding to homoscedastic within-group errors. |
| subset      | an optional expression indicating the subset of the rows of data that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.   |
| method      | a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "REML".   |
| na.action   | a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>lme</code> to print an error message and terminate if there are any incomplete observations.  |
| control     | a list of control values for the estimation algorithm to replace the default values returned by the function <code>lmeControl</code> . Defaults to an empty list.  |
| contrasts   | an optional list. See the <code>contrasts.arg</code> of <code>model.matrix.default</code> .  |
| keep.data   | logical: should the data argument (if supplied and a data frame) be saved as part of the model object?   |
| ...         | some methods for this generic require additional arguments. None are used in this method.  |
| evaluate    | If <code>TRUE</code> evaluate the new call else return the call.   |

### Value

An object of class "lme" representing the linear mixed-effects model fit. Generic functions such as `print`, `plot` and `summary` have methods to show the results of the fit. See `lmeObject` for the components of the fit. The functions `resid`, `coef`, `fitted`, `fixed.effects`, and `random.effects` can be used to extract some of its components.

### Note

The function does not do any scaling internally: the optimization will work best when the response is scaled so its variance is of the order of one.

### Author(s)

```

---

lme.groupedData

*LME fit from groupedData Object*

---

## Description

The response variable and primary covariate in formula(fixed) are used to construct the fixed effects model formula. This formula and the groupedData object are passed as the fixed and data arguments to lme.formula, together with any other additional arguments in the function call. See the documentation on lme.formula for a description of that function.

## Usage

```
## S3 method for class 'groupedData'
lme(fixed, data, random, correlation, weights,
    subset, method, na.action, control, contrasts, keep.data = TRUE)
```

**Arguments**

|             |  |
|-------------|--|
| fixed       | a data frame inheriting from class <code>"groupedData"</code> .  |
| data        | this argument is included for consistency with the generic function. It is ignored in this method function.  |
| random      | optionally, any of the following: (i) a one-sided formula of the form $\sim x_1 + \dots + x_n \mid g_1 / \dots / g_m$ , with $x_1 + \dots + x_n$ specifying the model for the random effects and $g_1 / \dots / g_m$ the grouping structure ( $m$ may be equal to 1, in which case no $/$ is required). The random effects formula will be repeated for all levels of grouping, in the case of multiple levels of grouping; (ii) a list of one-sided formulas of the form $\sim x_1 + \dots + x_n \mid g$ , with possibly different random effects models for each grouping level. The order of nesting will be assumed the same as the order of the elements in the list; (iii) a one-sided formula of the form $\sim x_1 + \dots + x_n$ , or a <code>pdMat</code> object with a formula (i.e. a non-NULL value for <code>formula(object)</code> ), or a list of such formulas or <code>pdMat</code> objects. In this case, the grouping structure formula will be derived from the data used to fit the linear mixed-effects model, which should inherit from class <code>groupedData</code> ; (iv) a named list of formulas or <code>pdMat</code> objects as in (iii), with the grouping factors as names. The order of nesting will be assumed the same as the order of the order of the elements in the list; (v) an <code>reStruct</code> object. See the documentation on <code>pdClasses</code> for a description of the available <code>pdMat</code> classes. Defaults to a formula consisting of the right hand side of <code>fixed</code> . |
| correlation | an optional <code>corStruct</code> object describing the within-group correlation structure. See the documentation of <code>corClasses</code> for a description of the available <code>corStruct</code> classes. Defaults to NULL, corresponding to no within-group correlations.  |
| weights     | an optional <code>varFunc</code> object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to <code>varFixed</code> , corresponding to fixed variance weights. See the documentation on <code>varClasses</code> for a description of the available <code>varFunc</code> classes. Defaults to NULL, corresponding to homoscedastic within-group errors.   |
| subset      | an optional expression indicating the subset of the rows of data that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.   |
| method      | a character string. If <code>"REML"</code> the model is fit by maximizing the restricted log-likelihood. If <code>"ML"</code> the log-likelihood is maximized. Defaults to <code>"REML"</code> .   |
| na.action   | a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>lme</code> to print an error message and terminate if there are any incomplete observations.  |
| control     | a list of control values for the estimation algorithm to replace the default values returned by the function <code>lmeControl</code> . Defaults to an empty list.  |
| contrasts   | an optional list. See the <code>contrasts.arg</code> of <code>model.matrix.default</code> .  |
| keep.data   | logical: should the data argument (if supplied and a data frame) be saved as part of the model object?   |

**Value**

an object of class `lme` representing the linear mixed-effects model fit. Generic functions such as `print`, `plot` and `summary` have methods to show the results of the fit. See `lmeObject` for the

components of the fit. The functions `resid`, `coef`, `fitted`, `fixed.effects`, and `random.effects` can be used to extract some of its components.

lme.lmList

*LME fit from lmList Object***Description**

If the random effects names defined in `random` are a subset of the `lmList` object coefficient names, initial estimates for the covariance matrix of the random effects are obtained (overwriting any values given in `random`). `formula(fixed)` and the `data` argument in the calling sequence used to obtain fixed are passed as the `fixed` and `data` arguments to `lme.formula`, together with any other additional arguments in the function call. See the documentation on `lme.formula` for a description of that function.

**Usage**

```
## S3 method for class 'lmList'
lme(fixed, data, random, correlation, weights, subset, method,
    na.action, control, contrasts, keep.data)
```

**Arguments**

- |             |  |
|-------------|--|
| fixed       | an object inheriting from class " <code>lmList</code> ", representing a list of <code>lm</code> fits with a common model.  |
| data        | this argument is included for consistency with the generic function. It is ignored in this method function.  |
| random      | an optional one-sided linear formula with no conditioning expression, or a <code>pdMat</code> object with a <code>formula</code> attribute. Multiple levels of grouping are not allowed with this method function. Defaults to a formula consisting of the right hand side of <code>formula(fixed)</code> .  |
| correlation | an optional <code>corStruct</code> object describing the within-group correlation structure. See the documentation of <code>corClasses</code> for a description of the available <code>corStruct</code> classes. Defaults to <code>NULL</code> , corresponding to no within-group correlations.  |
| weights     | an optional <code>varFunc</code> object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to <code>varFixed</code> , corresponding to fixed variance weights. See the documentation on <code>varClasses</code> for a description of the available <code>varFunc</code> classes. Defaults to <code>NULL</code> , corresponding to homoscedastic within-group errors. |
| subset      | an optional expression indicating the subset of the rows of data that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.   |
| method      | a character string. If <code>"REML"</code> the model is fit by maximizing the restricted log-likelihood. If <code>"ML"</code> the log-likelihood is maximized. Defaults to <code>"REML"</code> .   |
| na.action   | a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>lme</code> to print an error message and terminate if there are any incomplete observations.  |
| control     | a list of control values for the estimation algorithm to replace the default values returned by the function <code>lmeControl</code> . Defaults to an empty list.  |

|           |  |
|-----------|--|
| contrasts | an optional list. See the <code>contrasts.arg</code> of <code>model.matrix.default</code> .            |
| keep.data | logical: should the data argument (if supplied and a data frame) be saved as part of the model object? |

### Value

an object of class `lme` representing the linear mixed-effects model fit. Generic functions such as `print`, `plot` and `summary` have methods to show the results of the fit. lmeControl

---

*Specifying Control Values for lme Fit*

---

**Description**

The values supplied in the `lmeControl()` call replace the defaults, and a [list](#) with all settings (i.e., values for all possible arguments) is returned. The returned list is used as the control argument to the `lme` function.

**Usage**

```
lmeControl(maxIter = 50, msMaxIter = 50, tolerance = 1e-6, niterEM = 25,
           msMaxEval = 200,
           msTol = 1e-7, msVerbose = FALSE,
           returnObject = FALSE, gradHess = TRUE, apVar = TRUE,
           .relStep = .Machine$double.eps^(1/3), minAbsParApVar = 0.05,
           opt = c("nlminb", "optim"),
           optimMethod = "BFGS", natural = TRUE,
           sigma = NULL, ...)
```

**Arguments**

|                           |   |
|---------------------------|---|
| <code>maxIter</code>      | maximum number of iterations for the <code>lme</code> optimization algorithm. Default is 50.  |
| <code>msMaxIter</code>    | maximum number of iterations for the optimization step inside the <code>lme</code> optimization. Default is 50.   |
| <code>tolerance</code>    | tolerance for the convergence criterion in the <code>lme</code> algorithm. Default is 1e-6.   |
| <code>niterEM</code>      | number of iterations for the EM algorithm used to refine the initial estimates of the random effects variance-covariance coefficients. Default is 25.   |
| <code>msMaxEval</code>    | maximum number of evaluations of the objective function permitted for <code>nlminb</code> . Default is 200.   |
| <code>msTol</code>        | tolerance for the convergence criterion on the first iteration when <code>optim</code> is used. Default is 1e-7.  |
| <code>msVerbose</code>    | a logical value passed as the trace argument to <code>nlminb</code> or <code>optim</code> . Default is FALSE.   |
| <code>returnObject</code> | a logical value indicating whether the fitted object should be returned when the maximum number of iterations is reached without convergence of the algorithm. Default is FALSE.  |
| <code>gradHess</code>     | a logical value indicating whether numerical gradient vectors and Hessian matrices of the log-likelihood function should be used in the internal optimization. This option is only available when the correlation structure ( <code>corStruct</code> ) and the variance function structure ( <code>varFunc</code> ) have no "varying" parameters and the <code>pdMat</code> classes used in the random effects structure are <code>pdSymm</code> (general positive-definite), <code>pdDiag</code> (diagonal), <code>pdIdent</code> (multiple of the identity), or <code>pdCompSymm</code> (compound symmetry). Default is TRUE. |
| <code>apVar</code>        | a logical value indicating whether the approximate covariance matrix of the variance-covariance parameters should be calculated. Default is TRUE.   |

|                |   |
|----------------|---|
| .relStep       | relative step for numerical derivatives calculations. Default is <code>.Machine\$double.eps^(1/3)</code> .  |
| opt            | the optimizer to be used, either <code>"nlminb"</code> (the default) or <code>"optim"</code> .  |
| optimMethod    | character - the optimization method to be used with the <code>optim</code> optimizer. The default is <code>"BFGS"</code> . An alternative is <code>"L-BFGS-B"</code> .  |
| minAbsParApVar | numeric value - minimum absolute parameter value in the approximate variance calculation. The default is <code>0.05</code> .  |
| natural        | a logical value indicating whether the <code>pdNatural</code> parametrization should be used for general positive-definite matrices ( <code>pdSymm</code> ) in <code>reStruct</code> , when the approximate covariance matrix of the estimators is calculated. Default is <code>TRUE</code> . |
| sigma          | optionally a positive number to fix the residual error at. If <code>NULL</code> , as by default, or <code>0</code> , <code>sigma</code> is estimated.   |
| ...            | further named control arguments to be passed, depending on <code>opt</code> , to <code>nlminb</code> (those from <code>abs.tol</code> down) or <code>optim</code> (those except <code>trace</code> and <code>maxit</code> ; <code>reltol</code> is used only from the second iteration).      |

Value

a list with components for each of the possible arguments.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>; the `sigma` option: Siem Heisterkamp and Bert van Willigen.

|           |                          |
|-----------|--------------------------|
| lmeObject | <i>Fitted lme Object</i> |
|-----------|--------------------------|

---

Description

An object returned by the `lme` function, inheriting from class `lme` and representing a fitted linear mixed-effects model. Objects of this class have methods for the generic functions `anova`, `coef`, `fitted`, `fixed.effects`, `formula`, `getGroups`, `getResponse`, `intervals`, `logLik`, `pairs`, `plot`, `predict`, `print`, `random.effects`, `residuals`, `sigma`, `summary`, `update`, and `vcov`.

**Value**

The following components must be included in a legitimate lme object.

|              |  |
|--------------|--|
| apVar        | an approximate covariance matrix for the variance-covariance coefficients. If apVar = FALSE in the control values used in the call to lme, this component is NULL.   |
| call         | a list containing an image of the lme call that produced the object.   |
| coefficients | a list with two components, fixed and random, where the first is a vector containing the estimated fixed effects and the second is a list of matrices with the estimated random effects for each level of grouping. For each matrix in the random list, the columns refer to the random effects and the rows to the groups.  |
| contrasts    | a list with the contrasts used to represent factors in the fixed effects formula and/or random effects formula. This information is important for making predictions from a new data frame in which not all levels of the original factors are observed. If no factors are used in the lme model, this component will be an empty list.  |
| dims         | a list with basic dimensions used in the lme fit, including the components N - the number of observations in the data, Q - the number of grouping levels, qvec - the number of random effects at each level from innermost to outermost (last two values are equal to zero and correspond to the fixed effects and the response), ngrps - the number of groups at each level from innermost to outermost (last two values are one and correspond to the fixed effects and the response), and ncol - the number of columns in the model matrix for each level of grouping from innermost to outermost (last two values are equal to the number of fixed effects and one). |
| fitted       | a data frame with the fitted values as columns. The leftmost column corresponds to the population fixed effects (corresponding to the fixed effects only) and successive columns from left to right correspond to increasing levels of grouping.   |
| fixDF        | a list with components X and terms specifying the denominator degrees of freedom for, respectively, t-tests for the individual fixed effects and F-tests for the fixed-effects terms in the models.  |
| groups       | a data frame with the grouping factors as columns. The grouping level increases from left to right.  |
| logLik       | the (restricted) log-likelihood at convergence.  |
| method       | the estimation method: either "ML" for maximum likelihood, or "REML" for restricted maximum likelihood.  |
| modelStruct  | an object inheriting from class lmeStruct, representing a list of mixed-effects model components, such as reStruct, corStruct, and varFunc objects.  |
| numIter      | the number of iterations used in the iterative algorithm.  |
| residuals    | a data frame with the residuals as columns. The leftmost column corresponds to the population residuals and successive columns from left to right correspond to increasing levels of grouping.   |
| sigma        | the estimated within-group error standard deviation.   |
| varFix       | an approximate covariance matrix of the fixed effects estimates.   |

lmeStruct

*Linear Mixed-Effects Structure*

---

**Description**

A linear mixed-effects structure is a list of model components representing different sets of parameters in the linear mixed-effects model. An `lmeStruct` list must contain at least a `reStruct` object, but may also contain `corStruct` and `varFunc` objects. `NULL` arguments are not included in the `lmeStruct` list.

**Usage**

```
lmeStruct(reStruct, corStruct, varStruct)
```

**Arguments**

|                        |   |
|------------------------|---|
| <code>reStruct</code>  | a <code>reStruct</code> representing a random effects structure.  |
| <code>corStruct</code> | an optional <code>corStruct</code> object, representing a correlation structure. Default is <code>NULL</code> .     |
| <code>varStruct</code> | an optional <code>varFunc</code> object, representing a variance function structure. Default is <code>NULL</code> . |

**Value**

a list of model components determining the parameters to be estimated for the associated linear mixed-effects model.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[corClasses](#), [lme](#), [residuals.lmeStruct](#), [reStruct](#), [varFunc](#)

**Examples**

```
lms1 <- lmeStruct(reStruct(~age), corAR1(), varPower())
```

## lmList

*List of lm Objects with a Common Model***Description**

Data is partitioned according to the levels of the grouping factor `g` and individual `lm` fits are obtained for each data partition, using the model defined in object.

**Usage**

```
lmList(object, data, level, subset, na.action = na.fail,
        pool = TRUE, warn.lm = TRUE)
## S3 method for class 'lmList'
update(object, formula., ..., evaluate = TRUE)
## S3 method for class 'lmList'
print(x, pool, ...)
```

**Arguments**

|                        |   |
|------------------------|---|
| <code>object</code>    | For <code>lmList</code> , either a linear formula object of the form $y \sim x_1 + \dots + x_n \mid g$ or a <code>groupedData</code> object. In the formula object, <code>y</code> represents the response, $x_1, \dots, x_n$ the covariates, and <code>g</code> the grouping factor specifying the partitioning of the data according to which different <code>lm</code> fits should be performed. The grouping factor <code>g</code> may be omitted from the formula, in which case the grouping structure will be obtained from data, which must inherit from class <code>groupedData</code> . The method function <a href="#">lmList.groupedData</a> is documented separately. For the method <code>update.lmList</code> , <code>object</code> is an object inheriting from class <code>lmList</code> . |
| <code>formula</code>   | (used in <code>update.lmList</code> only) a two-sided linear formula with the common model for the individuals <code>lm</code> fits.  |
| <code>formula.</code>  | Changes to the formula – see <code>update.formula</code> for details.   |
| <code>data</code>      | a data frame in which to interpret the variables named in <code>object</code> .   |
| <code>level</code>     | an optional integer specifying the level of grouping to be used when multiple nested levels of grouping are present.  |
| <code>subset</code>    | an optional expression indicating which subset of the rows of data should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.   |
| <code>na.action</code> | a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>lmList</code> to print an error message and terminate if there are any incomplete observations.  |
| <code>pool</code>      | an optional logical value indicating whether a pooled estimate of the residual standard error should be used in calculations of standard deviations or standard errors for summaries.   |
| <code>warn.lm</code>   | <a href="#">logical</a> indicating if <code>lm()</code> errors (all of which are caught by <a href="#">tryCatch</a> ) should be signalled as a “summarizing” <a href="#">warning</a> .  |
| <code>x</code>         | an object inheriting from class <code>lmList</code> to be printed.  |
| <code>...</code>       | some methods for this generic require additional arguments. None are used in this method.   |
| <code>evaluate</code>  | If <code>TRUE</code> evaluate the new call else return the call.  |

**Value**

a list of `lm` objects with as many components as the number of groups defined by the grouping factor. Generic functions such as `coef`, `fixed.effects`, `lme`, `pairs`, `plot`, `predict`, `random.effects`, `summary`, and `update` have methods that can be applied to an `lmList` object.

**Examples**

```
fm1 <- lmList(distance ~ age | Subject, Orthodont)
summary(fm1)
```

---

|                                 |   |
|---------------------------------|---|
| <code>lmList.groupedData</code> | <i>lmList Fit from a groupedData Object</i> |
|---------------------------------|---|

---

**Description**

The response variable and primary covariate in `formula(object)` are used to construct the linear model formula. This formula and the `groupedData` object are passed as the `object` and `data` arguments to `lmList.formula`, together with any other additional arguments in the function call. See the documentation on `lmList.formula` for a description of that function.

**Usage**

```
## S3 method for class 'groupedData'
lmList(object, data, level, subset, na.action = na.fail,
        pool = TRUE, warn.lm = TRUE)
```

**Arguments**

|  |   |
|--|---|
| <code>object</code>                      | a data frame inheriting from class " <a href="#">groupedData</a> ".   |
| <code>data</code>                        | this argument is included for consistency with the generic function. It is ignored in this method function.   |
| <code>level</code>                       | an optional integer specifying the level of grouping to be used when multiple nested levels of grouping are present.  |
| <code>subset</code>                      | an optional expression indicating which subset of the rows of data should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default. |
| <code>na.action</code>                   | a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>lmList</code> to print an error message and terminate if there are any incomplete observations.  |
| <code>pool</code> , <code>warn.lm</code> | optional <a href="#">logicals</a> , see <a href="#">lmList</a> .  |

**Value**

a list of `lm` objects with as many components as the number of groups defined by the grouping factor. Generic functions such as `coef`, `fixed.effects`, `lme`, `pairs`, `plot`, `predict`, `random.effects`, `summary`, and `update` have methods that can be applied to an `lmList` object.

|--------|---|
| logDet | <i>Extract the Logarithm of the Determinant</i> |
|--------|---|

---

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `corStruct`, several `pdMat` classes, and `reStruct`.

**Usage**

```
logDet(object, ...)
```

**Arguments**

|                     |   |
|---------------------|---|
| <code>object</code> | any object from which a matrix, or list of matrices, can be extracted |
| <code>...</code>    | some methods for this generic function require additional arguments.  |

**Value**

will depend on the method function used; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

```

---

|                  |  |
|------------------|--|
| logDet.corStruct | <i>Extract corStruct Log-Determinant</i> |
|------------------|--|

---

## Description

This method function extracts the logarithm of the determinant of a square-root factor of the correlation matrix associated with `object`, or the sum of the log-determinants of square-root factors of the list of correlation matrices associated with `object`.

## Usage

```
## S3 method for class 'corStruct'  
logDet(object, covariate, ...)
```

## Arguments

|                        |   |
|------------------------|---|
| <code>object</code>    | an object inheriting from class " <a href="#">corStruct</a> ", representing a correlation structure.  |
| <code>covariate</code> | an optional covariate vector (matrix), or list of covariate vectors (matrices), at which values the correlation matrix, or list of correlation matrices, are to be evaluated. Defaults to <code>getCovariate(object)</code> . |
| <code>...</code>       | some methods for this generic require additional arguments. None are used in this method.   |

## Value

the log-determinant of a square-root factor of the correlation matrix associated with `object`, or the sum of the log-determinants of square-root factors of the list of correlation matrices associated with `object`.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

```

---

|              |  |
|--------------|--|
| logDet.pdMat | <i>Extract Log-Determinant from a pdMat Object</i> |
|--------------|--|

---

**Description**

This method function extracts the logarithm of the determinant of a square-root factor of the positive-definite matrix represented by object.

**Usage**

```
## S3 method for class 'pdMat'
logDet(object, ...)
```

**Arguments**

|        |   |
|--------|---|
| object | an object inheriting from class " <a href="#">pdMat</a> ", representing a positive definite matrix. |
| ...    | some methods for this generic require additional arguments. None are used in this method.           |

**Value**

the log-determinant of a square-root factor of the positive-definite matrix represented by object.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

pd1 <- pdSymm(diag(1:3))
logDet(pd1)
```

---

|                 |  |
|-----------------|--|
| logDet.reStruct | <i>Extract reStruct Log-Determinants</i> |
|-----------------|--|

---

**Description**

Calculates, for each of the pdMat components of object, the logarithm of the determinant of a square-root factor.

**Usage**

```
## S3 method for class 'reStruct'
logDet(object, ...)
```

**Arguments**

|        |   |
|--------|---|
| object | an object inheriting from class " <a href="#">reStruct</a> ", representing a random effects structure and consisting of a list of <code>pdMat</code> objects. |
| ...    | some methods for this generic require additional arguments. None are used in this method.   |

**Value**

a vector with the log-determinants of square-root factors of the `pdMat` components of object.

**Author(s)**

José Pinheiro

**See Also**

**Examples**

```
rs1 <- reStruct(list(A = pdSymm(diag(1:3), form = ~Score),
  B = pdDiag(2 * diag(4), form = ~Educ)))
logDet(rs1)
```

---

logLik.corStruct

---

*Extract corStruct Log-Likelihood*

---

**Description**

This method function extracts the component of a Gaussian log-likelihood associated with the correlation structure, which is equal to the negative of the logarithm of the determinant (or sum of the logarithms of the determinants) of the matrix (or matrices) represented by object.

**Usage**

```
## S3 method for class 'corStruct'
logLik(object, data, ...)
```

**Arguments**

|        |   |
|--------|---|
| object | an object inheriting from class " <a href="#">corStruct</a> ", representing a correlation structure.                          |
| data   | this argument is included to make this method function compatible with other <code>logLik</code> methods and will be ignored. |
| ...    | some methods for this generic require additional arguments. None are used in this method.                                     |

**Value**

the negative of the logarithm of the determinant (or sum of the logarithms of the determinants) of the correlation matrix (or matrices) represented by object.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[logDet.corStruct](#), [logLik.lme](#),

**Examples**

cs1 <- corAR1(0.2)
cs1 <- Initialize(cs1, data = Orthodont)
logLik(cs1)
```

---

logLik.glsStruct

*Log-Likelihood of a glsStruct Object*

---

**Description**

Pars is used to update the coefficients of the model components of object and the individual (restricted) log-likelihood contributions of each component are added together. The type of log-likelihood (restricted or not) is determined by the settings attribute of object.

**Usage**

```
## S3 method for class 'glsStruct'
logLik(object, Pars, conLin, ...)
```

**Arguments**

|        |   |
|--------|---|
| object | an object inheriting from class " <a href="#">glsStruct</a> ", representing a list of linear model components, such as <a href="#">corStruct</a> and " <a href="#">varFunc</a> " objects.   |
| Pars   | the parameter values at which the (restricted) log-likelihood is to be evaluated.   |
| conLin | an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying linear model. Defaults to attr(object, "conLin"). |
| ...    | some methods for this generic require additional arguments. None are used in this method.   |

**Value**

the (restricted) log-likelihood for the linear model described by object, evaluated at Pars.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

logLik.lme

---

*Log-Likelihood of an lme Object*

---

**Description**

If `REML=FALSE`, returns the log-likelihood value of the linear mixed-effects model represented by object evaluated at the estimated coefficients; else, the restricted log-likelihood evaluated at the estimated coefficients is returned.

**Usage**

```
## S3 method for class 'lme'
logLik(object, REML, ...)
```

**Arguments**

|        |   |
|--------|---|
| object | an object inheriting from class " <a href="#">lme</a> ", representing a fitted linear mixed-effects model.  |
| REML   | an optional logical value. If TRUE the restricted log-likelihood is returned, else, if FALSE, the log-likelihood is returned. Defaults to the method of estimation used, that is TRUE if and only object was fitted with method = " <code>REML</code> " (the default for these fitting functions) . |
| ...    | some methods for this generic require additional arguments. None are used in this method.   |

Value

the (restricted) log-likelihood of the model represented by object evaluated at the estimated coefficients.

---

logLik.reStruct

---

*Calculate reStruct Log-Likelihood*

---

**Description**

Calculates the log-likelihood, or restricted log-likelihood, of the Gaussian linear mixed-effects model represented by `object` and `conLin` (assuming spherical within-group covariance structure), evaluated at `coef(object)`. The `settings` attribute of `object` determines whether the log-likelihood, or the restricted log-likelihood, is to be calculated. The computational methods are described in Bates and Pinheiro (1998).

**Usage**

```
## S3 method for class 'reStruct'
logLik(object, conLin, ...)
```

**Arguments**

|                     |  |
|---------------------|--|
| <code>object</code> | an object inheriting from class " <b>reStruct</b> ", representing a random effects structure and consisting of a list of <code>pdMat</code> objects.   |
| <code>conLin</code> | a condensed linear model object, consisting of a list with components " <code>Xy</code> ", corresponding to a regression matrix ( <code>X</code> ) combined with a response vector ( <code>y</code> ), and " <code>logLik</code> ", corresponding to the log-likelihood of the underlying model. |
| <code>...</code>    | some methods for this generic require additional arguments. None are used in this method.  |

**Value**

the log-likelihood, or restricted log-likelihood, of linear mixed-effects model represented by `object` and `conLin`, evaluated at `coef{object}`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

| logLik.varFunc | <i>Extract varFunc logLik</i> |
|----------------|-------------------------------|

---

### Description

This method function extracts the component of a Gaussian log-likelihood associated with the variance function structure represented by object, which is equal to the sum of the logarithms of the corresponding weights.

### Usage

```
## S3 method for class 'varFunc'  
logLik(object, data, ...)
```

### Arguments

|        |  |
|--------|--|
| object | an object inheriting from class " <a href="#">varFunc</a> ", representing a variance function structure.         |
| data   | this argument is included to make this method function compatible with other logLik methods and will be ignored. |
| ...    | some methods for this generic require additional arguments. None are used in this method.                        |

### Value

the sum of the logarithms of the weights corresponding to the variance function structure represented by object.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

[logLik.lme](#)

### Examples

```
vf1 <- varPower(form = ~age)  
vf1 <- Initialize(vf1, Orthodont)  
coef(vf1) <- 0.1  
logLik(vf1)
```

The Machines data frame has 54 rows and 3 columns.

**Format**

This data frame contains the following columns:

**Worker** an ordered factor giving the unique identifier for the worker.

**Machine** a factor with levels A, B, and C identifying the machine brand.

**score** a productivity score.

**Details**

Data on an experiment to compare three brands of machines used in an industrial process are presented in Milliken and Johnson (p. 285, 1992). Six workers were chosen randomly among the employees of a factory to operate each machine three times. The response is an overall productivity score taking into account the number and quality of components produced.

MathAchieve

*Mathematics achievement scores***Description**

The MathAchieve data frame has 7185 rows and 6 columns.

**Format**

This data frame contains the following columns:

**School** an ordered factor identifying the school that the student attends

**Minority** a factor with levels No Yes indicating if the student is a member of a minority racial group.

**Sex** a factor with levels Male Female

**SES** a numeric vector of socio-economic status.

**MathAch** a numeric vector of mathematics achievement scores.

**MEANSES** a numeric vector of the mean SES for the school.

Details

Each row in this data frame contains the data for one student.

Examples

```
summary(MathAchieve)
```

---

|               |  |
|---------------|--|
| MathAchSchool | <i>School demographic data for MathAchieve</i> |
|---------------|--|

---

Description

The MathAchSchool data frame has 160 rows and 7 columns.

Format

This data frame contains the following columns:

- School** a factor giving the school on which the measurement is made.
- Size** a numeric vector giving the number of students in the school
- Sector** a factor with levels Public Catholic
- PRACAD** a numeric vector giving the percentage of students on the academic track
- DISCLIM** a numeric vector measuring the discrimination climate
- HIMINTY** a factor with levels 0 1
- MEANSES** a numeric vector giving the mean SES score.

Details

These variables give the school-level demographic data to accompany the MathAchieve data.

|        |                             |
|--------|-----------------------------|
| Matrix | <i>Assign Matrix Values</i> |
|--------|-----------------------------|

---

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include pdMat, pdBlocked, and reStruct.

Usage

```
matrix(object) <- value
```

Arguments

- object any object to which as.matrix can be applied.
- value a matrix, or list of matrices, with the same dimensions as as.matrix(object) with the new values to be assigned to the matrix associated with object.

**Value**

will depend on the method function; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`as.matrix`, also for examples, `matrix<- .pdMat`, `matrix<- .reStruct`.

---

|              |   |
|--------------|---|
| Matrix.pdMat | <i>Assign Matrix to a pdMat or pdBlocked Object</i> |
|--------------|---|

---

**Description**

The positive-definite matrix represented by `object` is replaced by `value`. If the original matrix had row and/or column names, the corresponding names for `value` can either be `NULL`, or a permutation of the original names.

**Usage**

```
## S3 replacement method for class 'pdMat'
matrix(object) <- value
## S3 replacement method for class 'pdBlocked'
matrix(object) <- value
```

**Arguments**

|                     |  |
|---------------------|--|
| <code>object</code> | an object inheriting from class " <code>pdMat</code> ", representing a positive definite matrix.   |
| <code>value</code>  | a matrix with the new values to be assigned to the positive-definite matrix represented by <code>object</code> . Must have the same dimensions as <code>as.matrix(object)</code> . |

**Value**

a `pdMat` or `pdBlocked` object similar to `object`, but with its coefficients modified to produce the matrix in `value`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`pdMat`, "`matrix<-`"

**Examples**

```
class(pd1 <- pdSymm(diag(3))) # "pdSymm" "pdMat"
matrix(pd1) <- diag(1:3)
pd1
```

---

|                 |                          |
|-----------------|--------------------------|
| Matrix.reStruct | Assign reStruct Matrices |
|-----------------|--------------------------|

---

**Description**

The individual matrices in value are assigned to each pdMat component of object, in the order they are listed. The new matrices must have the same dimensions as the matrices they are meant to replace.

**Usage**

```
## S3 replacement method for class 'reStruct'
matrix(object) <- value
```

**Arguments**

- object            an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects.
- value            a matrix, or list of matrices, with the new values to be assigned to the matrices associated with the pdMat components of object.

**Value**

an reStruct object similar to object, but with the coefficients of the individual pdMat components modified to produce the matrices listed in value.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

```
reStruct, pdMat, "matrix<-"
```

**Examples**

```
rs1 <- reStruct(list(Dog = ~day, Side = ~1), data = Pixel)
matrix(rs1) <- list(diag(2), 3)
```

|      |                    |
|------|--------------------|
| Meat | Tenderness of meat |
|------|--------------------|

---

**Description**

The Meat data frame has 30 rows and 4 columns.

**Format**

This data frame contains the following columns:

**Storage** an ordered factor specifying the storage treatment - 1 (0 days), 2 (1 day), 3 (2 days), 4 (4 days), 5 (9 days), and 6 (18 days)

**score** a numeric vector giving the tenderness score of beef roast.

**Block** an ordered factor identifying the muscle from which the roast was extracted with levels II < V < I < III < IV

**Pair** an ordered factor giving the unique identifier for each pair of beef roasts with levels II-1 < ... < IV-1

**Details**

Cochran and Cox (section 11.51, 1957) describe data from an experiment conducted at Iowa State College (Paul, 1943) to compare the effects of length of cold storage on the tenderness of beef roasts. Six storage periods ranging from 0 to 18 days were used. Thirty roasts were scored by four judges on a scale from 0 to 10, with the score increasing with tenderness. The response was the sum of all four scores. Left and right roasts from the same animal were grouped into pairs, which were further grouped into five blocks, according to the muscle from which they were extracted. Different storage periods were applied to each roast within a pair according to a balanced incomplete block design.

|------|--------------------------------------|
| Milk | <i>Protein content of cows' milk</i> |
|------|--------------------------------------|

---

**Description**

The Milk data frame has 1337 rows and 4 columns.

**Format**

This data frame contains the following columns:

**protein** a numeric vector giving the protein content of the milk.

**Time** a numeric vector giving the time since calving (weeks).

**Cow** an ordered factor giving a unique identifier for each cow.

**Diet** a factor with levels barley, barley+lupins, and lupins identifying the diet for each cow.

**Details**

Diggle, Liang, and Zeger (1994) describe data on the protein content of cows' milk in the weeks following calving. The cattle are grouped according to whether they are fed a diet with barley alone, with barley and lupins, or with lupins alone.

**Source**

Diggle, Peter J., Liang, Kung-Yee and Zeger, Scott L. (1994), *Analysis of longitudinal data*, Oxford University Press, Oxford.

---

`model.matrix.reStruct` *reStruct Model Matrix*

---

## Description

The model matrices for each element of `formula(object)`, calculated using data, are bound together column-wise. When multiple grouping levels are present (i.e. when `length(object) > 1`), the individual model matrices are combined from innermost (at the leftmost position) to outermost (at the rightmost position).

## Usage

```
## S3 method for class 'reStruct'  
model.matrix(object, data, contrast, ...)
```

## Arguments

|                       |   |
|-----------------------|---|
| <code>object</code>   | an object inheriting from class " <a href="#">reStruct</a> ", representing a random effects structure and consisting of a list of <code>pdMat</code> objects.   |
| <code>data</code>     | a data frame in which to evaluate the variables defined in <code>formula(object)</code> .   |
| <code>contrast</code> | an optional named list specifying the contrasts to be used for representing the factor variables in data. The components names should match the names of the variables in data for which the contrasts are to be specified. The components of this list will be used as the <code>contrasts</code> attribute of the corresponding factor. If missing, the default contrast specification is used. |
| <code>...</code>      | some methods for this generic require additional arguments. None are used in this method.   |

## Value

a matrix obtained by binding together, column-wise, the model matrices for each element of `formula(object)`.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

|        |   |
|--------|---|
| Muscle | <i>Contraction of heart muscle sections</i> |
|--------|---|

---

### Description

The Muscle data frame has 60 rows and 3 columns.

### Format

This data frame contains the following columns:

**Strip** an ordered factor indicating the strip of muscle being measured.

**conc** a numeric vector giving the concentration of CaCl<sub>2</sub>

**length** a numeric vector giving the shortening of the heart muscle strip.

### Details

Baumann and Waldvogel (1963) describe data on the shortening of heart muscle strips dipped in a CaCl<sub>2</sub> solution. The muscle strips are taken from the left auricle of a rat's heart.

### Source

|       |  |
|-------|--|
| Names | <i>Names Associated with an Object</i> |
|-------|--|

---

### Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: formula, modelStruct, pdBlocked, pdMat, and reStruct.

### Usage

```
Names(object, ...)
Names(object, ...) <- value
```

### Arguments

|        |  |
|--------|--|
| object | any object for which names can be extracted and/or assigned.         |
| ...    | some methods for this generic function require additional arguments. |
| value  | names to be assigned to object.                                      |

### Value

will depend on the method function used; see the appropriate documentation.

**SIDE EFFECTS**

On the left side of an assignment, sets the names associated with `object` to `value`, which must have an appropriate length.

**Note**

If names were generic, there would be no need for this generic function.

|---------------|-------------------------------------|
| Names.formula | <i>Extract Names from a formula</i> |
|---------------|-------------------------------------|

---

**Description**

This method function returns the names of the terms corresponding to the right hand side of `object` (treated as a linear formula), obtained as the column names of the corresponding `model.matrix`.

**Usage**

```
## S3 method for class 'formula'
Names(object, data, exclude, ...)
```

**Arguments**

|                      |   |
|----------------------|---|
| <code>object</code>  | an object inheriting from class " <a href="#">formula</a> ".  |
| <code>data</code>    | an optional data frame containing the variables specified in <code>object</code> . By default the variables are taken from the environment from which <code>Names.formula</code> is called. |
| <code>exclude</code> | an optional character vector with names to be excluded from the returned value. Default is <code>c("pi", ".")</code> .  |
| <code>...</code>     | some methods for this generic require additional arguments. None are used in this method.   |

**Value**

a character vector with the column names of the `model.matrix` corresponding to the right hand side of `object` which are not listed in `excluded`.

|-----------------|------------------------------------|
| Names.pdBlocked | <i>Names of a pdBlocked Object</i> |
|-----------------|------------------------------------|

---

**Description**

This method function extracts the first element of the Dimnames attribute, which contains the column names, for each block diagonal element in the matrix represented by object.

**Usage**

```
## S3 method for class 'pdBlocked'
Names(object, asList, ...)
```

**Arguments**

|        |   |
|--------|---|
| object | an object inheriting from class " <a href="#">pdBlocked</a> " representing a positive-definite matrix with block diagonal structure   |
| asList | a logical value. If TRUE a list with the names for each block diagonal element is returned. If FALSE a character vector with all column names is returned. Defaults to FALSE. |
| ...    | some methods for this generic require additional arguments. None are used in this method.   |

**Value**

if asList is FALSE, a character vector with column names of the matrix represented by object; otherwise, if asList is TRUE, a list with components given by the column names of the individual block diagonal elements in the matrix represented by object.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

---

`Names.pdMat`*Names of a pdMat Object*

---

### Description

This method function returns the first element of the `Dimnames` attribute of `object`, which contains the column names of the matrix represented by `object`.

### Usage

```
## S3 method for class 'pdMat'
Names(object, ...)
## S3 replacement method for class 'pdMat'
Names(object, ...) <- value
```

### Arguments

|                     |  |
|---------------------|--|
| <code>object</code> | an object inheriting from class " <a href="#">pdMat</a> ", representing a positive-definite matrix.  |
| <code>value</code>  | a character vector with the replacement values for the column and row names of the matrix represented by <code>object</code> . It must have length equal to the dimension of the matrix represented by <code>object</code> and, if names have been previously assigned to <code>object</code> , it must correspond to a permutation of the original names. |
| <code>...</code>    | some methods for this generic require additional arguments. None are used in this method.  |

### Value

if `object` has a `Dimnames` attribute then the first element of this attribute is returned; otherwise `NULL`.

### SIDE EFFECTS

On the left side of an assignment, sets the `Dimnames` attribute of `object` to `list(value, value)`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

|----------------|------------------------------------|
| Names.reStruct | <i>Names of an reStruct Object</i> |
|----------------|------------------------------------|

---

## Description

This method function extracts the column names of each of the positive-definite matrices represented the pdMat elements of object.

## Usage

```
## S3 method for class 'reStruct'  
Names(object, ...)  
## S3 replacement method for class 'reStruct'  
Names(object, ...) <- value
```

## Arguments

|        |   |
|--------|---|
| object | an object inheriting from class " <a href="#">reStruct</a> ", representing a random effects structure and consisting of a list of pdMat objects.                |
| value  | a list of character vectors with the replacement values for the names of the individual pdMat objects that form object. It must have the same length as object. |
| ...    | some methods for this generic require additional arguments. None are used in this method.   |

## Value

a list containing the column names of each of the positive-definite matrices represented by the pdMat elements of object.

## SIDE EFFECTS

On the left side of an assignment, sets the Names of the pdMat elements of object to the corresponding element of value.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

|------------|----------------------------------|
| needUpdate | <i>Check if Update is Needed</i> |
|------------|----------------------------------|

---

**Description**

This function is generic; method functions can be written to handle specific classes of objects. By default, it tries to extract a needUpdate attribute of object. If this is NULL or FALSE it returns FALSE; else it returns TRUE. Updating of objects usually takes place in iterative algorithms in which auxiliary quantities associated with the object, and not being optimized over, may change.

**Usage**

```
needUpdate(object)
```

**Arguments**

|        |            |
|--------|------------|
| object | any object |
|--------|------------|

**Value**

a logical value indicating whether object needs to be updated.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[needUpdate.modelStruct](#)

**Examples**

```
vf1 <- varExp()
vf1 <- Initialize(vf1, data = Orthodont)
needUpdate(vf1)
```

|------------------------|---|
| needUpdate.modelStruct | <i>Check if a modelStruct Object Needs Updating</i> |
|------------------------|---|

---

**Description**

This method function checks if any of the elements of object needs to be updated. Updating of objects usually takes place in iterative algorithms in which auxiliary quantities associated with the object, and not being optimized over, may change.

**Usage**

```
## S3 method for class 'modelStruct'
needUpdate(object)
```

Arguments

**object** an object inheriting from class "modelStruct", representing a list of model components, such as corStruct and varFunc objects.

Value

a logical value indicating whether any element of object needs to be updated.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

|--------------|------------------------------|
| Nitrendipene | <i>Assay of nitrendipene</i> |
|--------------|------------------------------|

---

Description

The Nitrendipene data frame has 89 rows and 4 columns.

Format

This data frame contains the following columns:

- activity** a numeric vector
- NIF** a numeric vector
- Tissue** an ordered factor with levels 2 < 1 < 3 < 4
- log.NIF** a numeric vector

Source

Bates, D. M. and Watts, D. G. (1988), *Nonlinear Regression Analysis and Its Applications*, Wiley, New York.

## Description

This generic function fits a nonlinear mixed-effects model in the formulation described in Lindstrom and Bates (1990) but allowing for nested random effects. The within-group errors are allowed to be correlated and/or have unequal variances.

## Usage

```
nlme(model, data, fixed, random, groups, start, correlation, weights,
      subset, method, na.action, naPattern, control, verbose)
```

## Arguments

- |        |   |
|--------|---|
| model  | a nonlinear model formula, with the response on the left of a $\sim$ operator and an expression involving parameters and covariates on the right, or an <code>nlsList</code> object. If data is given, all names used in the formula should be defined as parameters or variables in the data frame. The method function <code>nlme.nlsList</code> is documented separately.  |
| data   | an optional data frame containing the variables named in <code>model</code> , <code>fixed</code> , <code>random</code> , <code>correlation</code> , <code>weights</code> , <code>subset</code> , and <code>naPattern</code> . By default the variables are taken from the environment from which <code>nlme</code> is called.   |
| fixed  | a two-sided linear formula of the form $f_1 + \dots + f_n \sim x_1 + \dots + x_m$ , or a list of two-sided formulas of the form $f_1 \sim x_1 + \dots + x_m$ , with possibly different models for different parameters. The $f_1, \dots, f_n$ are the names of parameters included on the right hand side of <code>model</code> and the $x_1 + \dots + x_m$ expressions define linear models for these parameters (when the left hand side of the formula contains several parameters, they all are assumed to follow the same linear model, described by the right hand side expression). A 1 on the right hand side of the formula(s) indicates a single fixed effects for the corresponding parameter(s).  |
| random | optionally, any of the following: (i) a two-sided formula of the form $r_1 + \dots + r_n \sim x_1 + \dots + x_m \mid g_1 / \dots / g_Q$ , with $r_1, \dots, r_n$ naming parameters included on the right hand side of <code>model</code> , $x_1 + \dots + x_m$ specifying the random-effects model for these parameters and $g_1 / \dots / g_Q$ the grouping structure ( $Q$ may be equal to 1, in which case no $/$ is required). The random effects formula will be repeated for all levels of grouping, in the case of multiple levels of grouping; (ii) a two-sided formula of the form $r_1 + \dots + r_n \sim x_1 + \dots + x_m$ , a list of two-sided formulas of the form $r_1 \sim x_1 + \dots + x_m$ , with possibly different random-effects models for different parameters, a <code>pdMat</code> object with a two-sided formula, or list of two-sided formulas (i.e. a non-NULL value for <code>formula(random)</code> ), or a list of <code>pdMat</code> objects with two-sided formulas, or lists of two-sided formulas. In this case, the grouping structure formula will be given in <code>groups</code> , or derived from the data used to fit the nonlinear mixed-effects model, which should inherit from class <code>groupedData</code> ; (iii) a named list of formulas, lists of formulas, or <code>pdMat</code> objects as in (ii), with the grouping factors as names. The order of nesting will be assumed the same as the order of the elements in the list; (iv) an <code>reStruct</code> object. See the documentation on <code>pdClasses</code> for a description of the available <code>pdMat</code> classes. Defaults to <code>fixed</code> , resulting in all fixed effects having also random effects. |

|             |   |
|-------------|---|
| groups      | an optional one-sided formula of the form <code>~g1</code> (single level of nesting) or <code>~g1/.../gQ</code> (multiple levels of nesting), specifying the partitions of the data over which the random effects vary. <code>g1, ..., gQ</code> must evaluate to factors in data. The order of nesting, when multiple levels are present, is taken from left to right (i.e. <code>g1</code> is the first level, <code>g2</code> the second, etc.).   |
| start       | an optional numeric vector, or list of initial estimates for the fixed effects and random effects. If declared as a numeric vector, it is converted internally to a list with a single component <code>fixed</code> , given by the vector. The <code>fixed</code> component is required, unless the model function inherits from class <code>selfStart</code> , in which case initial values will be derived from a call to <code>nlsList</code> . An optional random component is used to specify initial values for the random effects and should consist of a matrix, or a list of matrices with length equal to the number of grouping levels. Each matrix should have as many rows as the number of groups at the corresponding level and as many columns as the number of random effects in that level. |
| correlation | an optional <code>corStruct</code> object describing the within-group correlation structure. See the documentation of <code>corClasses</code> for a description of the available <code>corStruct</code> classes. Defaults to <code>NULL</code> , corresponding to no within-group correlations.   |
| weights     | an optional <code>varFunc</code> object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to <code>varFixed</code> , corresponding to fixed variance weights. See the documentation on <code>varClasses</code> for a description of the available <code>varFunc</code> classes. Defaults to <code>NULL</code> , corresponding to homoscedastic within-group errors.  |
| subset      | an optional expression indicating the subset of the rows of data that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.  |
| method      | a character string. If <code>"REML"</code> the model is fit by maximizing the restricted log-likelihood. If <code>"ML"</code> the log-likelihood is maximized. Defaults to <code>"ML"</code> .  |
| na.action   | a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>nlme</code> to print an error message and terminate if there are any incomplete observations.  |
| naPattern   | an expression or formula object, specifying which returned values are to be regarded as missing.  |
| control     | a list of control values for the estimation algorithm to replace the default values returned by the function <code>nlmeControl</code> . Defaults to an empty list.  |
| verbose     | an optional logical value. If <code>TRUE</code> information on the evolution of the iterative algorithm is printed. Default is <code>FALSE</code> .   |

### Value

an object of class `nlme` representing the nonlinear mixed-effects model fit. Generic functions such as `print`, `plot` and `summary` have methods to show the results of the fit. See `nlmeObject` for the components of the fit. The functions `resid`, `coef`, `fitted`, `fixed.effects`, and `random.effects` can be used to extract some of its components.

### Note

The function does not do any scaling internally: the optimization will work best when the response is scaled so its variance is of the order of one.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

|--------------|-------------------------------------|
| nlme.nlsList | <i>NLME fit from nlsList Object</i> |
|--------------|-------------------------------------|

---

## Description

If the random effects names defined in `random` are a subset of the `lmList` object coefficient names, initial estimates for the covariance matrix of the random effects are obtained (overwriting any values given in `random`). `formula(fixed)` and the data argument in the calling sequence used to obtain fixed are passed as the `fixed` and `data` arguments to `nlme.formula`, together with any other additional arguments in the function call. See the documentation on `nlme.formula` for a description of that function.

## Usage

```
## S3 method for class 'nlsList'
nlme(model, data, fixed, random, groups, start, correlation, weights,
      subset, method, na.action, naPattern, control, verbose)
```

## Arguments

|                          |   |
|--------------------------|---|
| <code>model</code>       | an object inheriting from class " <code>nlsList</code> ", representing a list of nls fits with a common model.  |
| <code>data</code>        | this argument is included for consistency with the generic function. It is ignored in this method function.   |
| <code>fixed</code>       | this argument is included for consistency with the generic function. It is ignored in this method function.   |
| <code>random</code>      | an optional one-sided linear formula with no conditioning expression, or a <code>pdMat</code> object with a <code>formula</code> attribute. Multiple levels of grouping are not allowed with this method function. Defaults to a formula consisting of the right hand side of <code>formula(fixed)</code> .   |
| <code>groups</code>      | an optional one-sided formula of the form <code>~g1</code> (single level of nesting) or <code>~g1/.../gQ</code> (multiple levels of nesting), specifying the partitions of the data over which the random effects vary. <code>g1, ..., gQ</code> must evaluate to factors in data. The order of nesting, when multiple levels are present, is taken from left to right (i.e. <code>g1</code> is the first level, <code>g2</code> the second, etc.).   |
| <code>start</code>       | an optional numeric vector, or list of initial estimates for the fixed effects and random effects. If declared as a numeric vector, it is converted internally to a list with a single component <code>fixed</code> , given by the vector. The <code>fixed</code> component is required, unless the model function inherits from class <code>selfStart</code> , in which case initial values will be derived from a call to <code>nlsList</code> . An optional random component is used to specify initial values for the random effects and should consist of a matrix, or a list of matrices with length equal to the number of grouping levels. Each matrix should have as many rows as the number of groups at the corresponding level and as many columns as the number of random effects in that level. |
| <code>correlation</code> | an optional <code>corStruct</code> object describing the within-group correlation structure. See the documentation of <code>corClasses</code> for a description of the available <code>corStruct</code> classes. Defaults to <code>NULL</code> , corresponding to no within-group correlations.   |

|           |   |
|-----------|---|
| weights   | an optional varFunc object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to varFixed, corresponding to fixed variance weights. See the documentation on varClasses for a description of the available varFunc classes. Defaults to NULL, corresponding to homoscedastic within-group errors. |
| subset    | an optional expression indicating the subset of the rows of data that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.  |
| method    | a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "ML".  |
| na.action | a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes nlme to print an error message and terminate if there are any incomplete observations.  |
| naPattern | an expression or formula object, specifying which returned values are to be regarded as missing.  |
| control   | a list of control values for the estimation algorithm to replace the default values returned by the function nlmeControl. Defaults to an empty list.  |
| verbose   | an optional logical value. If TRUE information on the evolution of the iterative algorithm is printed. Default is FALSE.  |

### Value

an object of class nlme representing the linear mixed-effects model fit. Generic functions such as print, plot and summary have methods to show the results of the fit. See nlmeObject for the components of the fit. The functions resid, coef, fitted, fixed.effects, and random.effects can be used to extract some of its components.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### References

The computational methods follow on the general framework of Lindstrom, M.J. and Bates, D.M. (1988). The model formulation is described in Laird, N.M. and Ware, J.H. (1982). The variance-covariance parametrizations are described in <Pinheiro, J.C. and Bates., D.M. (1996). The different correlation structures available for the correlation argument are described in Box, G.E.P., Jenkins, G.M., and Reinsel G.C. (1994), Littell, R.C., Milliken, G.A., Stroup, W.W., and Wolfinger, R.D. (1996), and Venables, W.N. and Ripley, B.D. (2002). |-------------|------------------------------------|
| nlmeControl | <i>Control Values for nlme Fit</i> |
|-------------|------------------------------------|

---

## Description

The values supplied in the function call replace the defaults and a list with all possible arguments is returned. The returned list is used as the control argument to the nlme function.

## Usage

```
nlmeControl(maxIter, pnlsMaxIter, msMaxIter, minScale,
            tolerance, niterEM, pnlsTol, msTol,
            returnObject, msVerbose, gradHess, apVar, .relStep,
            minAbsParApVar = 0.05,
            opt = c("nlminb", "nlm"), natural = TRUE, sigma = NULL, ...)
```

## Arguments

|             |   |
|-------------|---|
| maxIter     | maximum number of iterations for the nlme optimization algorithm. Default is 50.  |
| pnlsMaxIter | maximum number of iterations for the PNLS optimization step inside the nlme optimization. Default is 7.   |
| msMaxIter   | maximum number of iterations for the nlm optimization step inside the nlme optimization. Default is 50.   |
| minScale    | minimum factor by which to shrink the default step size in an attempt to decrease the sum of squares in the PNLS step. Default 0.001.                 |
| tolerance   | tolerance for the convergence criterion in the nlme algorithm. Default is 1e-6.   |
| niterEM     | number of iterations for the EM algorithm used to refine the initial estimates of the random effects variance-covariance coefficients. Default is 25. |
| pnlsTol     | tolerance for the convergence criterion in PNLS step. Default is 1e-3.  |

|                |   |
|----------------|---|
| msTol          | tolerance for the convergence criterion in <code>nlm</code> , passed as the <code>gradtol</code> argument to the function (see documentation on <code>nlm</code> ). Default is $1e-7$ .   |
| returnObject   | a logical value indicating whether the fitted object should be returned when the maximum number of iterations is reached without convergence of the algorithm. Default is <code>FALSE</code> .  |
| msVerbose      | a logical value passed as the <code>trace</code> argument to <code>nlm</code> (see documentation on that function). Default is <code>FALSE</code> .   |
| gradHess       | a logical value indicating whether numerical gradient vectors and Hessian matrices of the log-likelihood function should be used in the <code>nlm</code> optimization. This option is only available when the correlation structure ( <code>corStruct</code> ) and the variance function structure ( <code>varFunc</code> ) have no "varying" parameters and the <code>pdMat</code> classes used in the random effects structure are <code>pdSymm</code> (general positive-definite), <code>pdDiag</code> (diagonal), <code>pdIdent</code> (multiple of the identity), or <code>pdCompSymm</code> (compound symmetry). Default is <code>TRUE</code> . |
| apVar          | a logical value indicating whether the approximate covariance matrix of the variance-covariance parameters should be calculated. Default is <code>TRUE</code> .   |
| .relStep       | relative step for numerical derivatives calculations. Default is <code>.Machine\$double.eps^(1/3)</code> .  |
| minAbsParApVar | numeric value - minimum absolute parameter value in the approximate variance calculation. The default is <code>0.05</code> .  |
| opt            | the optimizer to be used, either <code>"nlminb"</code> (the default) or <code>"nlm"</code> .  |
| natural        | a logical value indicating whether the <code>pdNatural</code> parametrization should be used for general positive-definite matrices ( <code>pdSymm</code> ) in <code>reStruct</code> , when the approximate covariance matrix of the estimators is calculated. Default is <code>TRUE</code> .   |
| sigma          | optionally a positive number to fix the residual error at. If <code>NULL</code> , as by default, or <code>0</code> , <code>sigma</code> is estimated.   |
| ...            | Further named control arguments to be passed to <code>nlminb</code> , where used ( <code>eval.max</code> and those from <code>abs.tol</code> down).   |

### Value

a list with components for each of the possible arguments.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>; the `sigma` option: Siem Heisterkamp and Bert van Willigen.

### See Also

`nlme`, `nlm`, `optim`, `nlmeStruct`

### Examples

```
# decrease the maximum number iterations in the ms call and
# request that information on the evolution of the ms iterations be printed
nlmeControl(msMaxIter = 20, msVerbose = TRUE)
```

---

|            |                           |
|------------|---------------------------|
| nlmeObject | <i>Fitted nlme Object</i> |
|------------|---------------------------|

---

### Description

An object returned by the `nlme` function, inheriting from class "nlme", also inheriting from class "lme", and representing a fitted nonlinear mixed-effects model. Objects of this class have methods for the generic functions `anova`, `coef`, `fitted`, `fixed.effects`, `formula`, `getGroups`, `getResponse`, `intervals`, `logLik`, `pairs`, `plot`, `predict`, `print`, `random.effects`, `residuals`, `summary`, and `update`.

### Value

The following components must be included in a legitimate "nlme" object.

|                           |   |
|---------------------------|---|
| <code>apVar</code>        | an approximate covariance matrix for the variance-covariance coefficients. If <code>apVar = FALSE</code> in the control values used in the call to <code>nlme</code> , this component is <code>NULL</code> .  |
| <code>call</code>         | a list containing an image of the <code>nlme</code> call that produced the object.  |
| <code>coefficients</code> | a list with two components, <code>fixed</code> and <code>random</code> , where the first is a vector containing the estimated fixed effects and the second is a list of matrices with the estimated random effects for each level of grouping. For each matrix in the <code>random</code> list, the columns refer to the random effects and the rows to the groups.   |
| <code>contrasts</code>    | a list with the contrasts used to represent factors in the fixed effects formula and/or random effects formula. This information is important for making predictions from a new data frame in which not all levels of the original factors are observed. If no factors are used in the <code>nlme</code> model, this component will be an empty list.   |
| <code>dims</code>         | a list with basic dimensions used in the <code>nlme</code> fit, including the components <code>N</code> - the number of observations in the data, <code>Q</code> - the number of grouping levels, <code>qvec</code> - the number of random effects at each level from innermost to outermost (last two values are equal to zero and correspond to the fixed effects and the response), <code>ngrps</code> - the number of groups at each level from innermost to outermost (last two values are one and correspond to the fixed effects and the response), and <code>ncol</code> - the number of columns in the model matrix for each level of grouping from innermost to outermost (last two values are equal to the number of fixed effects and one). |
| <code>fitted</code>       | a data frame with the fitted values as columns. The leftmost column corresponds to the population fixed effects (corresponding to the fixed effects only) and successive columns from left to right correspond to increasing levels of grouping.  |
| <code>fixDF</code>        | a list with components <code>X</code> and <code>terms</code> specifying the denominator degrees of freedom for, respectively, t-tests for the individual fixed effects and F-tests for the fixed-effects terms in the models.   |
| <code>groups</code>       | a data frame with the grouping factors as columns. The grouping level increases from left to right.   |
| <code>logLik</code>       | the (restricted) log-likelihood at convergence.   |
| <code>map</code>          | a list with components <code>fmap</code> , <code>rmap</code> , <code>rmapRe1</code> , and <code>bmap</code> , specifying various mappings for the fixed and random effects, used to generate predictions from the fitted object.  |

|             |  |
|-------------|--|
| method      | the estimation method: either "ML" for maximum likelihood, or "REML" for restricted maximum likelihood.  |
| modelStruct | an object inheriting from class nlmeStruct, representing a list of mixed-effects model components, such as reStruct, corStruct, and varFunc objects.   |
| numIter     | the number of iterations used in the iterative algorithm.  |
| residuals   | a data frame with the residuals as columns. The leftmost column corresponds to the population residuals and successive columns from left to right correspond to increasing levels of grouping. |
| sigma       | the estimated within-group error standard deviation.   |
| varFix      | an approximate covariance matrix of the fixed effects estimates.   |

[nlme](#), nlmeStruct

---

|            |  |
|------------|--|
| nlmeStruct | <i>Nonlinear Mixed-Effects Structure</i> |
|------------|--|

---

**Description**

A nonlinear mixed-effects structure is a list of model components representing different sets of parameters in the nonlinear mixed-effects model. An nlmeStruct list must contain at least a reStruct object, but may also contain corStruct and varFunc objects. NULL arguments are not included in the nlmeStruct list.

**Usage**

```
nlmeStruct(reStruct, corStruct, varStruct)
```

**Arguments**

|           |  |
|-----------|--|
| reStruct  | a reStruct representing a random effects structure.                                      |
| corStruct | an optional corStruct object, representing a correlation structure. Default is NULL.     |
| varStruct | an optional varFunc object, representing a variance function structure. Default is NULL. |

**Value**

a list of model components determining the parameters to be estimated for the associated nonlinear mixed-effects model.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[corClasses](#), [nlme](#), [residuals.nlmeStruct](#), [reStruct](#), [varFunc](#)

**Examples**

```
nls1 <- nlmeStruct(reStruct(~age), corAR1(), varPower())
```

---

nlsList

---

*List of nls Objects with a Common Model*

---

**Description**

Data is partitioned according to the levels of the grouping factor defined in `model` and individual nls fits are obtained for each data partition, using the model defined in `model`.

**Usage**

```
nlsList(model, data, start, control, level, subset,
        na.action = na.fail, pool = TRUE, warn.nls = NA)
## S3 method for class 'nlsList'
update(object, model., ..., evaluate = TRUE)
```

**Arguments**

|                        |   |
|------------------------|---|
| <code>object</code>    | an object inheriting from class <code>nlsList</code> , representing a list of fitted nls objects.   |
| <code>model</code>     | either a nonlinear model formula, with the response on the left of a <code>~</code> operator and an expression involving parameters, covariates, and a grouping factor separated by the <code> </code> operator on the right, or a <code>selfStart</code> function. The method function <a href="#">nlsList.selfStart</a> is documented separately. |
| <code>model.</code>    | changes to the model – see <a href="#">update.formula</a> for details.  |
| <code>data</code>      | a data frame in which to interpret the variables named in <code>model</code> .  |
| <code>start</code>     | an optional named list with initial values for the parameters to be estimated in <code>model</code> . It is passed as the <code>start</code> argument to each nls call and is required when the nonlinear function in <code>model</code> does not inherit from class <code>selfStart</code> .   |
| <code>control</code>   | a list of control values passed as the <code>control</code> argument to nls. Defaults to an empty list.   |
| <code>level</code>     | an optional integer specifying the level of grouping to be used when multiple nested levels of grouping are present.  |
| <code>subset</code>    | an optional expression indicating the subset of the rows of data that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.  |
| <code>na.action</code> | a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>nlsList</code> to print an error message and terminate if there are any incomplete observations.   |
| <code>pool</code>      | an optional logical value that is preserved as an attribute of the returned value. This will be used as the default for <code>pool</code> in calculations of standard deviations or standard errors for summaries.  |

|          |  |
|----------|--|
| warn.nls | <a href="#">logical</a> indicating if <a href="#">nls()</a> errors (all of which are caught by <a href="#">tryCatch</a> ) should be signalled as a “summarizing” <a href="#">warning</a> . |
| ...      | some methods for this generic require additional arguments. None are used in this method.  |
| evaluate | If TRUE evaluate the new call else return the call.  |

### Details

As [nls\(.\)](#) is called on each sub group, and convergence of these may be problematic, these calls happen with error catching.

Since [nlme](#) version 3.1-127 (2016-04), all the errors are caught (via [tryCatch](#)) and if present, a “summarizing” [warning](#) is stored as attribute of the resulting “nlsList” object and signalled unless suppressed by `warn.nls = FALSE` or currently also when `warn.nls = NA` (default) and [getOption\("show.error.messages"\)](#) is false.

[nlsList\(\)](#) originally had used [try\(\\*\)](#) (with its default `silent=FALSE`) and hence all errors were printed to the console *unless* the global option `show.error.messages` was set to true. This still works, but has been *deprecated*.

### Value

a list of nls objects with as many components as the number of groups defined by the grouping factor. Generic functions such as `coef`, `fixed.effects`, `lme`, `pairs`, `plot`, `predict`, `random.effects`, `summary`, and `update` have methods that can be applied to an [nlsList](#) object.

### Examples

```
fm1 <- nlsList(uptake ~ SSasymOff(conc, Asym, lrc, c0),
  data = C02, start = c(Asym = 30, lrc = -4.5, c0 = 52))
summary(fm1)
cfm1 <- confint(fm1) # via profiling each % FIXME: only *one* message instead of one *each*
stopifnot((i.ok <- which(sapply(cfm1, class) == "matrix"))
  %in% c(2:4,6:9, 12))
## where as (some of) the others gave errors during profile re-fitting :
str(cfm1[- i.ok])
```

---

`nlsList.selfStart`

*nlsList Fit from a selfStart Function*

---

### Description

The response variable and primary covariate in `formula(data)` are used together with `model` to construct the nonlinear model formula. This is used in the `nls` calls and, because a `selfStarting` model function can calculate initial estimates for its parameters from the data, no starting estimates need to be provided.

**Usage**

```
## S3 method for class 'selfStart'
nlsList(model, data, start, control, level, subset,
        na.action = na.fail, pool = TRUE, warn.nls = NA)
```

**Arguments**

|   |   |
|---|---|
| <code>model</code>                        | a " <a href="#">selfStart</a> " model function, which calculates initial estimates for the model parameters from data.  |
| <code>data</code>                         | a data frame in which to interpret the variables in <code>model</code> . Because no grouping factor can be specified in <code>model</code> , <code>data</code> must inherit from class " <a href="#">groupedData</a> ".   |
| <code>start</code>                        | an optional named list with initial values for the parameters to be estimated in <code>model</code> . It is passed as the <code>start</code> argument to each <code>nls</code> call and is required when the nonlinear function in <code>model</code> does not inherit from class <code>selfStart</code> .                |
| <code>control</code>                      | a list of control values passed as the <code>control</code> argument to <code>nls</code> . Defaults to an empty list.   |
| <code>level</code>                        | an optional integer specifying the level of grouping to be used when multiple nested levels of grouping are present.  |
| <code>subset</code>                       | an optional expression indicating the subset of the rows of <code>data</code> that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default. |
| <code>na.action</code>                    | a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>nlsList</code> to print an error message and terminate if there are any incomplete observations.   |
| <code>pool</code> , <code>warn.nls</code> | optional <a href="#">logicals</a> , see <a href="#">nlsList</a> .   |

**Value**

a list of `nls` objects with as many components as the number of groups defined by the grouping factor. A `NULL` value is assigned to the components corresponding to clusters for which the `nls` algorithm failed to converge. Generic functions such as `coef`, `fixed.effects`, `lme`, `pairs`, `plot`, `predict`, `random.effects`, `summary`, and `update` have methods that can be applied to an `nlsList` object.

**See Also**

[selfStart](#), [groupedData](#), [nls](#), [nlsList](#), [nlme.nlsList](#), [nlsList.formula](#)

**Examples**

```
fm1 <- nlsList(SSasymptOff, CO2)

```

Oats

*Split-plot Experiment on Varieties of Oats***Description**

The Oats data frame has 72 rows and 4 columns.

**Format**

This data frame contains the following columns:

**Block** an ordered factor with levels VI < V < III < IV < II < I

**Variety** a factor with levels Golden Rain Marvellous Victory

**nitro** a numeric vector

**yield** a numeric vector

**Details**

These data have been introduced by Yates (1935) as an example of a split-plot design. The treatment structure used in the experiment was a  $3 \times 4$  full factorial, with three varieties of oats and four concentrations of nitrogen. The experimental units were arranged into six blocks, each with three whole-plots subdivided into four subplots. The varieties of oats were assigned randomly to the whole-plots and the concentrations of nitrogen to the subplots. All four concentrations of nitrogen were used on each whole-plot.

Orthodont

*Growth curve data on an orthodontic measurement***Description**

The Orthodont data frame has 108 rows and 4 columns of the change in an orthodontic measurement over time for several young subjects.

**Format**

This data frame contains the following columns:

**distance** a numeric vector of distances from the pituitary to the pterygomaxillary fissure (mm). These distances are measured on x-ray images of the skull.

**age** a numeric vector of ages of the subject (yr).

**Subject** an ordered factor indicating the subject on which the measurement was made. The levels are labelled M01 to M16 for the males and F01 to F13 for the females. The ordering is by increasing average distance within sex.

**Sex** a factor with levels Male and Female

### Details

Investigators at the University of North Carolina Dental School followed the growth of 27 children (16 males, 11 females) from age 8 until age 14. Every two years they measured the distance between the pituitary and the pterygomaxillary fissure, two points that are easily identified on x-ray exposures of the side of the head.

|       |                                    |
|-------|------------------------------------|
| Ovary | <i>Counts of Ovarian Follicles</i> |
|-------|------------------------------------|

---

### Description

The Ovary data frame has 308 rows and 3 columns.

### Format

This data frame contains the following columns:

**Mare** an ordered factor indicating the mare on which the measurement is made.

**Time** time in the estrus cycle. The data were recorded daily from 3 days before ovulation until 3 days after the next ovulation. The measurement times for each mare are scaled so that the ovulations for each mare occur at times 0 and 1.

**follicles** the number of ovarian follicles greater than 10 mm in diameter.

### Details

Pierson and Ginther (1987) report on a study of the number of large ovarian follicles detected in different mares at several times in their estrus cycles.

Oxboys

---

*Heights of Boys in Oxford*

---

**Description**

The Oxboys data frame has 234 rows and 4 columns.

**Format**

This data frame contains the following columns:

**Subject** an ordered factor giving a unique identifier for each boy in the experiment

**age** a numeric vector giving the standardized age (dimensionless)

**height** a numeric vector giving the height of the boy (cm)

**Occasion** an ordered factor - the result of converting age from a continuous variable to a count so these slightly unbalanced data can be analyzed as balanced.

**Details**

These data are described in Goldstein (1987) as data on the height of a selection of boys from Oxford, England versus a standardized age.

---

Oxide

---

*Variability in Semiconductor Manufacturing*

---

**Description**

The Oxide data frame has 72 rows and 5 columns.

**Format**

This data frame contains the following columns:

**Source** a factor with levels 1 and 2

**Lot** a factor giving a unique identifier for each lot.

**Wafer** a factor giving a unique identifier for each wafer within a lot.

**Site** a factor with levels 1, 2, and 3

**Thickness** a numeric vector giving the thickness of the oxide layer.

## Details

These data are described in Littell et al. (1996, p. 155) as coming “from a passive data collection study in the semiconductor industry where the objective is to estimate the variance components to determine the assignable causes of the observed variability.” The observed response is the thickness of the oxide layer on silicon wafers, measured at three different sites of each of three wafers selected from each of eight lots sampled from the population of lots.

|                   |   |
|-------------------|---|
| pairs.compareFits | <i>Pairs Plot of compareFits Object</i> |
|-------------------|---|

---

## Description

Scatter plots of the values being compared are generated for each pair of coefficients in `x`. Different symbols (colors) are used for each object being compared and values corresponding to the same group are joined by a line, to facilitate comparison of fits. If only two coefficients are present, the trellis function `xypplot` is used; otherwise the trellis function `splom` is used.

## Usage

```
## S3 method for class 'compareFits'
pairs(x, subset, key, ...)
```

## Arguments

|                     |   |
|---------------------|---|
| <code>x</code>      | an object of class <code>compareFits</code> .   |
| <code>subset</code> | an optional logical or integer vector specifying which rows of <code>x</code> should be used in the plots. If missing, all rows are used.   |
| <code>key</code>    | an optional logical value, or list. If <code>TRUE</code> , a legend is included at the top of the plot indicating which symbols (colors) correspond to which objects being compared. If <code>FALSE</code> , no legend is included. If given as a list, <code>key</code> is passed down as an argument to the trellis function generating the plots ( <code>splom</code> or <code>xypplot</code> ). Defaults to <code>TRUE</code> . |
| <code>...</code>    | optional arguments passed down to the trellis function generating the plots.  |

## Value

Pairwise scatter plots of the values being compared, with different symbols (colors) used for each object under comparison.

## Author(s)

José Pinheiro and Douglas Bates

**Examples**

```
fm1 <- lmList(Orthodont)
fm2 <- lme(Orthodont)
pairs(compareFits(coef(fm1), coef(fm2)))
```

---

pairs.lme

*Pairs Plot of an lme Object*

---

**Description**

Diagnostic plots for the linear mixed-effects fit are obtained. The `form` argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a `|` operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. The expression on the right hand side of the formula, before a `|` operator, must evaluate to a data frame with at least two columns. If the data frame has two columns, a scatter plot of the two variables is displayed (the Trellis function `xyplot` is used). Otherwise, if more than two columns are present, a scatter plot matrix with pairwise scatter plots of the columns in the data frame is displayed (the Trellis function `splom` is used).

**Usage**

```
## S3 method for class 'lme'
pairs(x, form, label, id, idLabels, grid, ...)
```

**Arguments**

|                    |  |
|--------------------|--|
| <code>x</code>     | an object inheriting from class <code>"lme"</code> , representing a fitted linear mixed-effects model.   |
| <code>form</code>  | an optional one-sided formula specifying the desired type of plot. Any variable present in the original data frame used to obtain <code>x</code> can be referenced. In addition, <code>x</code> itself can be referenced in the formula using the symbol <code>"."</code> . Conditional expressions on the right of a <code> </code> operator can be used to define separate panels in a Trellis display. The expression on the right hand side of <code>form</code> , and to the left of the <code> </code> operator, must evaluate to a data frame with at least two columns. Default is <code>~ coef(.)</code> , corresponding to a pairs plot of the coefficients evaluated at the innermost level of nesting. |
| <code>label</code> | an optional character vector of labels for the variables in the pairs plot.  |
| <code>id</code>    | an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for an outlier test based on the Mahalanobis distances of the estimated random effects. Groups with random effects distances greater than the $1 - \text{value}$ percentile of the appropriate chi-square distribution are identified in the plot using <code>idLabels</code> . If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify points in the plot. If missing, no points are identified.   |

|          |   |
|----------|---|
| idLabels | an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the points identified according to id. If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified points. Default is the innermost grouping factor. |
| grid     | an optional logical value indicating whether a grid should be added to plot. Default is FALSE.  |
| ...      | optional arguments passed to the Trellis plot function.   |

**Value**

a diagnostic Trellis plot.

PBG

*Effect of Phenylbiguanide on Blood Pressure***Description**

The PBG data frame has 60 rows and 5 columns.

**Format**

This data frame contains the following columns:

**deltaBP** a numeric vector

**dose** a numeric vector

**Run** an ordered factor with levels T5 < T4 < T3 < T2 < T1 < P5 < P3 < P2 < P4 < P1

**Treatment** a factor with levels MDL 72222 Placebo

**Rabbit** an ordered factor with levels 5 < 3 < 2 < 4 < 1

**Details**

Data on an experiment to examine the effect of a antagonist MDL 72222 on the change in blood pressure experienced with increasing dosage of phenylbiguanide are described in Ludbrook (1994) and analyzed in Venables and Ripley (2002, section 10.3). Each of five rabbits was exposed to increasing doses of phenylbiguanide after having either a placebo or the HD5-antagonist MDL 72222 administered.

pdBlocked

*Positive-Definite Block Diagonal Matrix***Description**

This function is a constructor for the pdBlocked class, representing a positive-definite block-diagonal matrix. Each block-diagonal element of the underlying matrix is itself a positive-definite matrix and is represented internally as an individual pdMat object. When value is numeric(0), a list of uninitialized pdMat objects, a list of one-sided formulas, or a list of vectors of character strings, object is returned as an uninitialized pdBlocked object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the coef or matrix replacement functions. If value is a list of initialized pdMat objects, object will be constructed from the list obtained by applying as.matrix to each of the pdMat elements of value. Finally, if value is a list of numeric vectors, they are assumed to represent the unrestricted coefficients of the block-diagonal elements of the underlying positive-definite matrix.

**Usage**

```
pdBlocked(value, form, nam, data, pdClass)
```

**Arguments**

|         |   |
|---------|---|
| value   | an optional list with elements to be used as the value argument to other pdMat constructors. These include: pdMat objects, positive-definite matrices, one-sided linear formulas, vectors of character strings, or numeric vectors. All elements in the list must be similar (e.g. all one-sided formulas, or all numeric vectors). Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object. |
| form    | an optional list of one-sided linear formulas specifying the row/column names for the block-diagonal elements of the matrix represented by object. Because factors may be present in form, the formulas needs to be evaluated on a data.frame to resolve the names they define. This argument is ignored when value is a list of one-sided formulas. Defaults to NULL.  |
| nam     | an optional list of vector of character strings specifying the row/column names for the block-diagonal elements of the matrix represented by object. Each of its components must have length equal to the dimension of the corresponding block-diagonal element and unreplicated elements. This argument is ignored when value is a list of vector of character strings. Defaults to NULL.                          |
| data    | an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on any factors appearing in the formulas. Defaults to the parent frame from which the function was called.   |
| pdClass | an optional vector of character strings naming the pdMat classes to be assigned to the individual blocks in the underlying matrix. If a single class is specified, it is used for all block-diagonal elements. This argument will only be used when value is missing, or its elements are not pdMat objects. Defaults to "pdSymm".  |

**Value**

a pdBlocked object representing a positive-definite block-diagonal matrix, also inheriting from class pdMat.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**Examples**

```
pd1 <- pdBlocked(list(diag(1:2), diag(c(0.1, 0.2, 0.3))),
                  nam = list(c("A", "B"), c("a1", "a2", "a3")))
pd1
```

pdClasses

*Positive-Definite Matrix Classes***Description**

Standard classes of positive-definite matrices (pdMat) structures available in the nlme package.

**Value**

Available standard classes:

|            |  |
|------------|--|
| pdSymm     | general positive-definite matrix, with no additional structure   |
| pdLogChol  | general positive-definite matrix, with no additional structure, using a log-Cholesky parameterization  |
| pdDiag     | diagonal   |
| pdIdent    | multiple of an identity  |
| pdCompSymm | compound symmetry structure (constant diagonal and constant off-diagonal elements)   |
| pdBlocked  | block-diagonal matrix, with diagonal blocks of any "atomic" pdMat class  |
| pdNatural  | general positive-definite matrix in natural parametrization (i.e. parametrized in terms of standard deviations and correlations). The underlying coefficients are not unrestricted, so this class should NOT be used for optimization. |

**Note**

Users may define their own pdMat classes by specifying a constructor function and, at a minimum, methods for the functions pdConstruct, pdMatrix and coef. For examples of these functions, see the methods for classes pdSymm and pdDiag.

**Author(s)**

pdCompSymm

*Positive-Definite Matrix with Compound Symmetry Structure***Description**

This function is a constructor for the `pdCompSymm` class, representing a positive-definite matrix with compound symmetry structure (constant diagonal and constant off-diagonal elements). The underlying matrix is represented by 2 unrestricted parameters. When `value` is `numeric(0)`, an uninitialized `pdMat` object, a one-sided formula, or a vector of character strings, object is returned as an uninitialized `pdCompSymm` object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions. If `value` is an initialized `pdMat` object, object will be constructed from `as.matrix(value)`. Finally, if `value` is a numeric vector of length 2, it is assumed to represent the unrestricted coefficients of the underlying positive-definite matrix.

**Usage**

```
pdCompSymm(value, form, nam, data)
```

**Arguments**

|                    |  |
|--------------------|--|
| <code>value</code> | an optional initialization value, which can be any of the following: a <code>pdMat</code> object, a positive-definite matrix, a one-sided linear formula (with variables separated by <code>+</code> ), a vector of character strings, or a numeric vector of length 2. Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object.  |
| <code>form</code>  | an optional one-sided linear formula specifying the row/column names for the matrix represented by object. Because factors may be present in <code>form</code> , the formula needs to be evaluated on a <code>data.frame</code> to resolve the names it defines. This argument is ignored when <code>value</code> is a one-sided formula. Defaults to <code>NULL</code> .  |
| <code>nam</code>   | an optional vector of character strings specifying the row/column names for the matrix represented by object. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when <code>value</code> is a vector of character strings. Defaults to <code>NULL</code> .  |
| <code>data</code>  | an optional data frame in which to evaluate the variables named in <code>value</code> and <code>form</code> . It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If <code>NULL</code> , no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called. |

**Value**

a `pdCompSymm` object representing a positive-definite matrix with compound symmetry structure, also inheriting from class `pdMat`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer, esp. p. 161.

pd1
```

---

pdConstruct

*Construct pdMat Objects*

---

**Description**

This function is an alternative constructor for the `pdMat` class associated with object and is mostly used internally in other functions. See the documentation on the principal constructor function, generally with the same name as the `pdMat` class of object.

**Usage**

```
pdConstruct(object, value, form, nam, data, ...)
```

**Arguments**

|                     |  |
|---------------------|--|
| <code>object</code> | an object inheriting from class <code>pdMat</code> , representing a positive definite matrix.  |
| <code>value</code>  | an optional initialization value, which can be any of the following: a <code>pdMat</code> object, a positive-definite matrix, a one-sided linear formula (with variables separated by <code>+</code> ), a vector of character strings, or a numeric vector. Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object.  |
| <code>form</code>   | an optional one-sided linear formula specifying the row/column names for the matrix represented by <code>object</code> . Because factors may be present in <code>form</code> , the formula needs to be evaluated on a <code>data.frame</code> to resolve the names it defines. This argument is ignored when <code>value</code> is a one-sided formula. Defaults to <code>NULL</code> .                          |
| <code>nam</code>    | an optional vector of character strings specifying the row/column names for the matrix represented by <code>object</code> . It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when <code>value</code> is a vector of character strings. Defaults to <code>NULL</code> .  |
| <code>data</code>   | an optional data frame in which to evaluate the variables named in <code>value</code> and <code>form</code> . It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If <code>NULL</code> , no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called. |
| <code>...</code>    | optional arguments for some methods.   |

**Value**

a `pdMat` object representing a positive-definite matrix, inheriting from the same classes as `object`.

pd1 <- pdSymm()
pdConstruct(pd1, diag(1:4))
```

---

pdConstruct.pdBlocked    *Construct pdBlocked Objects*

---

**Description**

This function give an alternative constructor for the pdBlocked class, representing a positive-definite block-diagonal matrix. Each block-diagonal element of the underlying matrix is itself a positive-definite matrix and is represented internally as an individual pdMat object. When value is numeric(0), a list of uninitialized pdMat objects, a list of one-sided formulas, or a list of vectors of character strings, object is returned as an uninitialized pdBlocked object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the coef or matrix replacement functions. If value is a list of initialized pdMat objects, object will be constructed from the list obtained by applying as.matrix to each of the pdMat elements of value. Finally, if value is a list of numeric vectors, they are assumed to represent the unrestricted coefficients of the block-diagonal elements of the underlying positive-definite matrix.

**Usage**

```
## S3 method for class 'pdBlocked'
pdConstruct(object, value, form, nam, data, pdClass,
...)
```

**Arguments**

|        |   |
|--------|---|
| object | an object inheriting from class "pdBlocked", representing a positive definite block-diagonal matrix.  |
| value  | an optional list with elements to be used as the value argument to other pdMat constructors. These include: pdMat objects, positive-definite matrices, one-sided linear formulas, vectors of character strings, or numeric vectors. All elements in the list must be similar (e.g. all one-sided formulas, or all numeric vectors). Defaults to numeric(0), corresponding to an uninitialized object. |
| form   | an optional list of one-sided linear formula specifying the row/column names for the block-diagonal elements of the matrix represented by object. Because factors may be present in form, the formulas needs to be evaluated on a data.frame to resolve the names they defines. This argument is ignored when value is a list of one-sided formulas. Defaults to NULL.                                |
| nam    | an optional list of vector of character strings specifying the row/column names for the block-diagonal elements of the matrix represented by object. Each of its components must have length equal to the dimension of the corresponding block-diagonal element and unreplicated elements. This argument is ignored when value is a list of vector of character strings. Defaults to NULL.            |

|         |   |
|---------|---|
| data    | an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called. |
| pdClass | an optional vector of character strings naming the pdMat classes to be assigned to the individual blocks in the underlying matrix. If a single class is specified, it is used for all block-diagonal elements. This argument will only be used when value is missing, or its elements are not pdMat objects. Defaults to "pdSymm".                                      |
| ...     | some methods for this generic require additional arguments. None are used in this method.   |

### Value

a pdBlocked object representing a positive-definite block-diagonal matrix, also inheriting from class pdMat.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### References

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

### See Also

[as.matrix.pdMat](#), [coef.pdMat](#), [pdBlocked](#), [pdClasses](#), [pdConstruct](#), [matrix<- .pdMat](#)

### Examples

```
pd1 <- pdBlocked(list(c("A","B"), c("a1", "a2", "a3")))
pdConstruct(pd1, list(diag(1:2), diag(c(0.1, 0.2, 0.3))))
```

---

pdDiag

*Diagonal Positive-Definite Matrix*

---

### Description

This function is a constructor for the pdDiag class, representing a diagonal positive-definite matrix. If the matrix associated with object is of dimension  $n$ , it is represented by  $n$  unrestricted parameters, given by the logarithm of the square-root of the diagonal values. When value is `numeric(0)`, an uninitialized pdMat object, a one-sided formula, or a vector of character strings, object is returned as an uninitialized pdDiag object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions. If value is an initialized pdMat object, object will be constructed from `as.matrix(value)`. Finally, if value is a numeric vector, it is assumed to represent the unrestricted coefficients of the underlying positive-definite matrix.

### Usage

```
pdDiag(value, form, nam, data)
```

**Arguments**

|       |  |
|-------|--|
| value | an optional initialization value, which can be any of the following: a pdMat object, a positive-definite matrix, a one-sided linear formula (with variables separated by +), a vector of character strings, or a numeric vector of length equal to the dimension of the underlying positive-definite matrix. Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object. |
| form  | an optional one-sided linear formula specifying the row/column names for the matrix represented by object. Because factors may be present in form, the formula needs to be evaluated on a data.frame to resolve the names it defines. This argument is ignored when value is a one-sided formula. Defaults to NULL.  |
| nam   | an optional vector of character strings specifying the row/column names for the matrix represented by object. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when value is a vector of character strings. Defaults to NULL.   |
| data  | an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called.                      |

**Value**

a pdDiag object representing a diagonal positive-definite matrix, also inheriting from class pdMat.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

pd1
```

---

pdFactor

*Square-Root Factor of a Positive-Definite Matrix*

---

**Description**

A square-root factor of the positive-definite matrix represented by object is obtained. Letting  $\Sigma$  denote a positive-definite matrix, a square-root factor of  $\Sigma$  is any square matrix  $L$  such that  $\Sigma = L'L$ . This function extracts  $L$ .

**Usage**

```
pdFactor(object)
```

**Arguments**

**object** an object inheriting from class `pdMat`, representing a positive definite matrix, which must have been initialized (i.e. `length(coef(object)) > 0`).

**Value**

a vector with a square-root factor of the positive-definite matrix associated with `object` stacked column-wise.

**Note**

This function is used intensively in optimization algorithms and its value is returned as a vector for efficiency reasons. The `pdMatrix` function can be used to obtain square-root factors in matrix form.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

```

---

pdIdent

*Multiple of the Identity Positive-Definite Matrix*

---

**Description**

This function is a constructor for the `pdIdent` class, representing a multiple of the identity positive-definite matrix. The matrix associated with object is represented by 1 unrestricted parameter, given by the logarithm of the square-root of the diagonal value. When `value` is `numeric(0)`, an uninitialized `pdMat` object, a one-sided formula, or a vector of character strings, object is returned as an uninitialized `pdIdent` object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions. If `value` is an initialized `pdMat` object, object will be constructed from `as.matrix(value)`. Finally, if `value` is a numeric value, it is assumed to represent the unrestricted coefficient of the underlying positive-definite matrix.

**Usage**

```
pdIdent(value, form, nam, data)
```

**Arguments**

|       |   |
|-------|---|
| value | an optional initialization value, which can be any of the following: a pdMat object, a positive-definite matrix, a one-sided linear formula (with variables separated by +), a vector of character strings, or a numeric value. Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object.   |
| form  | an optional one-sided linear formula specifying the row/column names for the matrix represented by object. Because factors may be present in form, the formula needs to be evaluated on a data.frame to resolve the names it defines. This argument is ignored when value is a one-sided formula. Defaults to NULL.   |
| nam   | an optional vector of character strings specifying the row/column names for the matrix represented by object. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when value is a vector of character strings. Defaults to NULL.  |
| data  | an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called. |

**Value**

a pdIdent object representing a multiple of the identity positive-definite matrix, also inheriting from class pdMat.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

```
pd1 <- pdIdent(4 * diag(3), nam = c("A", "B", "C"))
pd1
```

## Description

This function is a constructor for the `pdLogChol` class, representing a general positive-definite matrix. If the matrix associated with `object` is of dimension  $n$ , it is represented by  $n(n + 1)/2$  unrestricted parameters, using the log-Cholesky parametrization described in Pinheiro and Bates (1996).

- When `value` is `numeric(0)`, an uninitialized `pdMat` object, a one-sided formula, or a character vector, `object` is returned as an *uninitialized* `pdLogChol` object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions.
- If `value` is an *initialized* `pdMat` object, `object` will be constructed from `as.matrix(value)`.
- Finally, if `value` is a numeric vector, it is assumed to represent the unrestricted coefficients of the matrix-logarithm parametrization of the underlying positive-definite matrix.

## Usage

```
pdLogChol(value, form, nam, data)
```

## Arguments

|                    |  |
|--------------------|--|
| <code>value</code> | an optional initialization value, which can be any of the following: a <code>pdMat</code> object, a positive-definite matrix, a one-sided linear formula (with variables separated by <code>+</code> ), a vector of character strings, or a numeric vector. Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object.  |
| <code>form</code>  | an optional one-sided linear formula specifying the row/column names for the matrix represented by <code>object</code> . Because factors may be present in <code>form</code> , the formula needs to be evaluated on a data frame to resolve the names it defines. This argument is ignored when <code>value</code> is a one-sided formula. Defaults to <code>NULL</code> .                                       |
| <code>nam</code>   | an optional character vector specifying the row/column names for the matrix represented by <code>object</code> . It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when <code>value</code> is a character vector. Defaults to <code>NULL</code> .  |
| <code>data</code>  | an optional data frame in which to evaluate the variables named in <code>value</code> and <code>form</code> . It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If <code>NULL</code> , no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called. |

## Details

Internally, the `pdLogChol` representation of a symmetric positive definite matrix is a vector starting with the logarithms of the diagonal of the Choleski factorization of that matrix followed by its upper triangular portion.

## Value

a `pdLogChol` object representing a general positive-definite matrix, also inheriting from class `pdMat`.

|-------|---------------------------------|
| pdMat | <i>Positive-Definite Matrix</i> |
|-------|---------------------------------|

---

## Description

This function gives an alternative way of constructing an object inheriting from the pdMat class named in pdClass, or from data.class(object) if object inherits from pdMat, and is mostly used internally in other functions. See the documentation on the principal constructor function, generally with the same name as the pdMat class of object.

## Usage

```
pdMat(value, form, nam, data, pdClass)
```

## Arguments

- |       |   |
|-------|---|
| value | an optional initialization value, which can be any of the following: a pdMat object, a positive-definite matrix, a one-sided linear formula (with variables separated by +), a vector of character strings, or a numeric vector. Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object.  |
| form  | an optional one-sided linear formula specifying the row/column names for the matrix represented by object. Because factors may be present in form, the formula needs to be evaluated on a data.frame to resolve the names it defines. This argument is ignored when value is a one-sided formula. Defaults to NULL.   |
| nam   | an optional vector of character strings specifying the row/column names for the matrix represented by object. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when value is a vector of character strings. Defaults to NULL.  |
| data  | an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called. |

**pdClass** an optional character string naming the pdMat class to be assigned to the returned object. This argument will only be used when value is not a pdMat object. Defaults to "pdSymm".

### Value

a pdMat object representing a positive-definite matrix, inheriting from the class named in pdClass, or from class(object), if object inherits from pdMat.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

pd1
```

---

pdMatrix

*Extract Matrix or Square-Root Factor from a pdMat Object*

---

### Description

The positive-definite matrix represented by object, or a square-root factor of it is obtained. Letting  $\Sigma$  denote a positive-definite matrix, a square-root factor of  $\Sigma$  is any square matrix  $L$  such that  $\Sigma = L'L$ . This function extracts  $S$  or  $L$ .

### Usage

```
pdMatrix(object, factor)
```

### Arguments

**object** an object inheriting from class pdMat, representing a positive definite matrix.

**factor** an optional logical value. If TRUE, a square-root factor of the positive-definite matrix represented by object is returned; else, if FALSE, the positive-definite matrix is returned. Defaults to FALSE.

### Value

if fact is FALSE the positive-definite matrix represented by object is returned; else a square-root of the positive-definite matrix is returned.

---

pdNatural

*General Positive-Definite Matrix in Natural Parametrization*

---

**Description**

This function is a constructor for the `pdNatural` class, representing a general positive-definite matrix, using a natural parametrization. If the matrix associated with object is of dimension  $n$ , it is represented by  $n(n+1)/2$  parameters. Letting  $\sigma_{ij}$  denote the  $ij$ -th element of the underlying positive definite matrix and  $\rho_{ij} = \sigma_{ij} / \sqrt{\sigma_{ii}\sigma_{jj}}$ ,  $i \neq j$  denote the associated "correlations", the "natural" parameters are given by  $\sqrt{\sigma_{ii}}$ ,  $i = 1, \dots, n$  and  $\log((1 + \rho_{ij})/(1 - \rho_{ij}))$ ,  $i \neq j$ . Note that all natural parameters are individually unrestricted, but not jointly unrestricted (meaning that not all unrestricted vectors would give positive-definite matrices). Therefore, this parametrization should NOT be used for optimization. It is mostly used for deriving approximate confidence intervals on parameters following the optimization of an objective function. When value is `numeric(0)`, an uninitialized `pdMat` object, a one-sided formula, or a vector of character strings, object is returned as an uninitialized `pdSymm` object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions. If value is an initialized `pdMat` object, object will be constructed from `as.matrix(value)`. Finally, if value is a numeric vector, it is assumed to represent the natural parameters of the underlying positive-definite matrix.

**Usage**

```
pdNatural(value, form, nam, data)
```

**Arguments**

|       |   |
|-------|---|
| value | an optional initialization value, which can be any of the following: a <code>pdMat</code> object, a positive-definite matrix, a one-sided linear formula (with variables separated by <code>+</code> ), a vector of character strings, or a numeric vector. Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object.   |
| form  | an optional one-sided linear formula specifying the row/column names for the matrix represented by object. Because factors may be present in form, the formula needs to be evaluated on a <code>data.frame</code> to resolve the names it defines. This argument is ignored when value is a one-sided formula. Defaults to <code>NULL</code> .  |
| nam   | an optional vector of character strings specifying the row/column names for the matrix represented by object. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when value is a vector of character strings. Defaults to <code>NULL</code> .  |
| data  | an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If <code>NULL</code> , no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called. |

**Value**

a pdNatural object representing a general positive-definite matrix in natural parametrization, also inheriting from class pdMat.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer, esp. p. 162.

pdSymm

*General Positive-Definite Matrix*

---

**Description**

This function is a constructor for the pdSymm class, representing a general positive-definite matrix. If the matrix associated with object is of dimension  $n$ , it is represented by  $n(n + 1)/2$  unrestricted parameters, using the matrix-logarithm parametrization described in Pinheiro and Bates (1996). When value is `numeric(0)`, an uninitialized pdMat object, a one-sided formula, or a vector of character strings, object is returned as an uninitialized pdSymm object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions. If value is an initialized pdMat object, object will be constructed from `as.matrix(value)`. Finally, if value is a numeric vector, it is assumed to represent the unrestricted coefficients of the matrix-logarithm parametrization of the underlying positive-definite matrix.

**Usage**

```
pdSymm(value, form, nam, data)
```

**Arguments**

|       |   |
|-------|---|
| value | an optional initialization value, which can be any of the following: a pdMat object, a positive-definite matrix, a one-sided linear formula (with variables separated by +), a vector of character strings, or a numeric vector. Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object.    |
| form  | an optional one-sided linear formula specifying the row/column names for the matrix represented by object. Because factors may be present in form, the formula needs to be evaluated on a data.frame to resolve the names it defines. This argument is ignored when value is a one-sided formula. Defaults to NULL. |

|      |   |
|------|---|
| nam  | an optional vector of character strings specifying the row/column names for the matrix represented by object. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when value is a vector of character strings. Defaults to NULL.  |
| data | an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called. |

Value

a pdSymm object representing a general positive-definite matrix, also inheriting from class pdMat.

|-----------|-------------------------------|
| Phenobarb | <i>Phenobarbital Kinetics</i> |
|-----------|-------------------------------|

---

Description

The Phenobarb data frame has 744 rows and 7 columns.

Format

- This data frame contains the following columns:
- Subject** an ordered factor identifying the infant.
  - Wt** a numeric vector giving the birth weight of the infant (kg).
  - Apgar** an ordered factor giving the 5-minute Apgar score for the infant. This is an indication of health of the newborn infant.
  - ApgarInd** a factor indicating whether the 5-minute Apgar score is < 5 or >= 5.
  - time** a numeric vector giving the time when the sample is drawn or drug administered (hr).
  - dose** a numeric vector giving the dose of drug administered (ug/kg).
  - conc** a numeric vector giving the phenobarbital concentration in the serum (ug/L).

## Details

Data from a pharmacokinetics study of phenobarbital in neonatal infants. During the first few days of life the infants receive multiple doses of phenobarbital for prevention of seizures. At irregular intervals blood samples are drawn and serum phenobarbital concentrations are determined. The data were originally given in Grasela and Donn(1985) and are analyzed in Boeckmann, Sheiner and Beal (1994), in Davidian and Giltinan (1995), and in Littell et al. (1996).

phenoModel

*Model function for the Phenobarb data*

---

## Description

A model function for a model used with the Phenobarb data. This function uses compiled C code to improve execution speed.

## Usage

```
phenoModel(Subject, time, dose, lCl, lV)
```

## Arguments

|         |   |
|---------|---|
| Subject | an integer vector of subject identifiers. These should be sorted in increasing order.                                 |
| time    | numeric. A vector of the times at which the sample was drawn or the drug administered (hr).                           |
| dose    | numeric. A vector of doses of drug administered (ug/kg).  |
| lCl     | numeric. A vector of values of the natural log of the clearance parameter according to Subject and time.              |
| lV      | numeric. A vector of values of the natural log of the effective volume of distribution according to Subject and time. |

## Details

See the details section of [Phenobarb](#) for a description of the model function that phenoModel evaluates.

**Value**

a numeric vector of predicted phenobarbital concentrations.

---

**Description**

The Pixel data frame has 102 rows and 4 columns of data on the pixel intensities of CT scans of dogs over time

**Format**

This data frame contains the following columns:

**Dog** a factor with levels 1 to 10 designating the dog on which the scan was made

**Side** a factor with levels L and R designating the side of the dog being scanned

**day** a numeric vector giving the day post injection of the contrast on which the scan was made

**pixel** a numeric vector of pixel intensities

**Source**

Pinheiro, J. C. and Bates, D. M. (2000) *Mixed-effects Models in S and S-PLUS*, Springer.

**Examples**

```
fm1 <- lme(pixel ~ day + I(day^2), data = Pixel,
           random = list(Dog = ~ day, Side = ~ 1))
summary(fm1)
VarCorr(fm1)
```

plot.ACF

*Plot an ACF Object***Description**

an xyplot of the autocorrelations versus the lags, with `type = "h"`, is produced. If `alpha > 0`, curves representing the critical limits for a two-sided test of level `alpha` for the autocorrelations are added to the plot.

**Usage**

```
## S3 method for class 'ACF'
plot(x, alpha, xlab, ylab, grid, ...)
```

**Arguments**

|                         |  |
|-------------------------|--|
| <code>x</code>          | an object inheriting from class <code>ACF</code> , consisting of a data frame with two columns named <code>lag</code> and <code>ACF</code> , representing the autocorrelation values and the corresponding lags.   |
| <code>alpha</code>      | an optional numeric value with the significance level for testing if the autocorrelations are zero. Lines corresponding to the lower and upper critical values for a test of level <code>alpha</code> are added to the plot. Default is <code>0</code> , in which case no lines are plotted. |
| <code>xlab, ylab</code> | optional character strings with the x- and y-axis labels. Default respectively to <code>"Lag"</code> and <code>"Autocorrelation"</code> .  |
| <code>grid</code>       | an optional logical value indicating whether a grid should be added to plot. Default is <code>FALSE</code> .   |
| <code>...</code>        | optional arguments passed to the <code>xyplot</code> function.   |

**Value**

an xyplot Trellis plot.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**Examples**

```
fm1 <- lme(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary)
plot(ACF(fm1, maxLag = 10), alpha = 0.01)
```

---

plot.augPred

---

*Plot an augPred Object*

---

### Description

A Trellis xyplot of predictions versus the primary covariate is generated, with a different panel for each value of the grouping factor. Predicted values are joined by lines, with different line types (colors) being used for each level of grouping. Original observations are represented by circles.

### Usage

```
## S3 method for class 'augPred'
plot(x, key, grid, ...)
```

### Arguments

|      |  |
|------|--|
| x    | an object of class " <a href="#">augPred</a> ".  |
| key  | an optional logical value, or list. If TRUE, a legend is included at the top of the plot indicating which symbols (colors) correspond to which prediction levels. If FALSE, no legend is included. If given as a list, key is passed down as an argument to the <code>trellis</code> function generating the plots (xyplot). Defaults to TRUE. |
| grid | an optional logical value indicating whether a grid should be added to plot. Default is FALSE.   |
| ...  | optional arguments passed down to the <code>trellis</code> function generating the plots.  |

### Value

A Trellis plot of predictions versus the primary covariate, with panels determined by the grouping factor.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

### Examples

```
fm1 <- lme(Orthodont)
plot(augPred(fm1, level = 0:1, length.out = 2))
```

---

|                  |                                  |
|------------------|----------------------------------|
| plot.compareFits | <i>Plot a compareFits Object</i> |
|------------------|----------------------------------|

---

### Description

A Trellis dotplot of the values being compared, with different rows per group, is generated, with a different panel for each coefficient. Different symbols (colors) are used for each object being compared.

### Usage

```
## S3 method for class 'compareFits'
plot(x, subset, key, mark, ...)
```

### Arguments

|        |   |
|--------|---|
| x      | an object of class " <a href="#">compareFits</a> ".   |
| subset | an optional logical or integer vector specifying which rows of x should be used in the plots. If missing, all rows are used.  |
| key    | an optional logical value, or list. If TRUE, a legend is included at the top of the plot indicating which symbols (colors) correspond to which objects being compared. If FALSE, no legend is included. If given as a list, key is passed down as an argument to the trellis function generating the plots (dotplot). Defaults to TRUE. |
| mark   | an optional numeric vector, of length equal to the number of coefficients being compared, indicating where vertical lines should be drawn in the plots. If missing, no lines are drawn.   |
| ...    | optional arguments passed down to the trellis function generating the plots.  |

### Value

A Trellis dotplot of the values being compared, with rows determined by the groups and panels by the coefficients.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

fm2 <- lme(Orthodont)
plot(compareFits(coef(fm1), coef(fm2)))

## End(Not run)
```

plot.gls

*Plot a gls Object***Description**

Diagnostic plots for the linear model fit are obtained. The `form` argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a `|` operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. If `form` is a one-sided formula, histograms of the variable on the right hand side of the formula, before a `|` operator, are displayed (the Trellis function `histogram` is used). If `form` is two-sided and both its left and right hand side variables are numeric, scatter plots are displayed (the Trellis function `xyplot` is used). Finally, if `form` is two-sided and its left hand side variable is a factor, box-plots of the right hand side variable by the levels of the left hand side variable are displayed (the Trellis function `bwplot` is used).

**Usage**

```
## S3 method for class 'gls'
plot(x, form, abline, id, idLabels, idResType, grid, ...)
```

**Arguments**

- |                        |  |
|------------------------|--|
| <code>x</code>         | an object inheriting from class <code>"gls"</code> , representing a generalized least squares fitted linear model.   |
| <code>form</code>      | an optional formula specifying the desired type of plot. Any variable present in the original data frame used to obtain <code>x</code> can be referenced. In addition, <code>x</code> itself can be referenced in the formula using the symbol <code>"."</code> . Conditional expressions on the right of a <code> </code> operator can be used to define separate panels in a Trellis display. Default is <code>resid(., type = "p") ~ fitted(.)</code> , corresponding to a plot of the standardized residuals versus fitted values, both evaluated at the innermost level of nesting. |
| <code>abline</code>    | an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.   |
| <code>id</code>        | an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized residuals. Observations with absolute standardized residuals greater than the $1 - \text{value}/2$ quantile of the standard normal distribution are identified in the plot using <code>idLabels</code> . If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified.        |
| <code>idLabels</code>  | an optional vector, or one-sided formula. If given as a vector, it is converted to character mode and used to label the observations identified according to <code>id</code> . If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character mode and used to label the identified observations. Default is the innermost grouping factor.  |
| <code>idResType</code> | an optional character string specifying the type of residuals to be used in identifying outliers, when <code>id</code> is a numeric value. If <code>"pearson"</code> , the standardized  |

residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson".

**grid** an optional logical value indicating whether a grid should be added to plot. Default depends on the type of Trellis plot used: if xyplot defaults to TRUE, else defaults to FALSE.

**...** optional arguments passed to the Trellis plot function.

**Value**

a diagnostic Trellis plot.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[gls](#), [xyplot](#), [bwplot](#), [histogram](#)

**Examples**

```
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary,
          correlation = corAR1(form = ~ 1 | Mare))
# standardized residuals versus fitted values by Mare
plot(fm1, resid(., type = "p") ~ fitted(.) | Mare, abline = 0)
# box-plots of residuals by Mare
plot(fm1, Mare ~ resid(.))
# observed versus fitted values by Mare
plot(fm1, follicles ~ fitted(.) | Mare, abline = c(0,1))
```

---

plot.intervals.lmList *Plot lmList Confidence Intervals*

---

**Description**

A Trellis dot-plot of the confidence intervals on the linear model coefficients is generated, with a different panel for each coefficient. Rows in the dot-plot correspond to the names of the `lm` components of the `lmList` object used to produce `x`. The lower and upper confidence limits are connected by a line segment and the estimated coefficients are marked with a "+". The Trellis function `dotplot` is used in this method function.

**Usage**

```
## S3 method for class 'intervals.lmList'
plot(x, ...)
```

**Arguments**

- `x` an object inheriting from class "`intervals.lmList`", representing confidence intervals and estimates for the coefficients in the `lm` components of the `lmList` object used to produce `x`.
- `...` optional arguments passed to the Trellis `dotplot` function.

**Value**

a Trellis plot with the confidence intervals on the coefficients of the individual `lm` components of the `lmList` that generated `x`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`intervals.lmList`, `lmList`, `dotplot`

**Examples**

```
fm1 <- lmList(distance ~ age | Subject, Orthodont)
plot(intervals(fm1))
```

---

plot.lme

*Plot an lme or nls object*

---

**Description**

Diagnostic plots for the linear mixed-effects fit are obtained. The `form` argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a `|` operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. If `form` is a one-sided formula, histograms of the variable on the right hand side of the formula, before a `|` operator, are displayed (the Trellis function `histogram` is used). If `form` is two-sided and both its left and right hand side variables are numeric, scatter plots are displayed (the Trellis function `xyplot` is used). Finally, if `form` is two-sided and its left hand side variable is a factor, box-plots of the right hand side variable by the levels of the left hand side variable are displayed (the Trellis function `bwplot` is used).

**Usage**

```
## S3 method for class 'lme'
plot(x, form, abline, id, idLabels, idResType, grid, ...)
## S3 method for class 'nls'
plot(x, form, abline, id, idLabels, idResType, grid, ...)
```

**Arguments**

|                        |   |
|------------------------|---|
| <code>x</code>         | an object inheriting from class <code>"lme"</code> , representing a fitted linear mixed-effects model, or from <code>nls</code> , representing an fitted nonlinear least squares model.   |
| <code>form</code>      | an optional formula specifying the desired type of plot. Any variable present in the original data frame used to obtain <code>x</code> can be referenced. In addition, <code>x</code> itself can be referenced in the formula using the symbol <code>". "</code> . Conditional expressions on the right of a <code> </code> operator can be used to define separate panels in a Trellis display. Default is <code>resid(., type = "p") ~ fitted(.)</code> , corresponding to a plot of the standardized residuals versus fitted values, both evaluated at the innermost level of nesting.                     |
| <code>abline</code>    | an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.  |
| <code>id</code>        | an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized, or normalized residuals. Observations with absolute standardized (normalized) residuals greater than the $1 - \text{value}/2$ quantile of the standard normal distribution are identified in the plot using <code>idLabels</code> . If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified. |
| <code>idLabels</code>  | an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the observations identified according to <code>id</code> . If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified observations. Default is the innermost grouping factor.   |
| <code>idResType</code> | an optional character string specifying the type of residuals to be used in identifying outliers, when <code>id</code> is a numeric value. If <code>"pearson"</code> , the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if <code>"normalized"</code> , the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to <code>"pearson"</code> .            |
| <code>grid</code>      | an optional logical value indicating whether a grid should be added to plot. Default depends on the type of Trellis plot used: if <code>xypLOT</code> defaults to <code>TRUE</code> , else defaults to <code>FALSE</code> .   |
| <code>...</code>       | optional arguments passed to the Trellis plot function.   |

**Value**

a diagnostic Trellis plot.

plot.lmList

---

*Plot an lmList Object*

---

## Description

Diagnostic plots for the linear model fits corresponding to the  $x$  components are obtained. The `form` argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a `|` operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. If `form` is a one-sided formula, histograms of the variable on the right hand side of the formula, before a `|` operator, are displayed (the Trellis function `histogram` is used). If `form` is two-sided and both its left and right hand side variables are numeric, scatter plots are displayed (the Trellis function `xyplot` is used). Finally, if `form` is two-sided and its left hand side variable is a factor, box-plots of the right hand side variable by the levels of the left hand side variable are displayed (the Trellis function `bwplot` is used).

## Usage

```
## S3 method for class 'lmList'
plot(x, form, abline, id, idLabels, grid, ...)
```

## Arguments

- |                     |   |
|---------------------|---|
| <code>x</code>      | an object inheriting from class " <code>lmList</code> ", representing a list of <code>lm</code> objects with a common model.  |
| <code>form</code>   | an optional formula specifying the desired type of plot. Any variable present in the original data frame used to obtain <code>x</code> can be referenced. In addition, <code>x</code> itself can be referenced in the formula using the symbol <code>"."</code> . Conditional expressions on the right of a <code> </code> operator can be used to define separate panels in a Trellis display. Default is <code>resid(., type = "pool") ~ fitted(.)</code> , corresponding to a plot of the standardized residuals (using a pooled estimate for the residual standard error) versus fitted values. |
| <code>abline</code> | an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.  |
| <code>id</code>     | an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized residuals. Observations with absolute standardized residuals greater than the $1 - \text{value}/2$ quantile of the standard normal distribution are identified in the plot using <code>idLabels</code> . If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified.                   |

|          |  |
|----------|--|
| idLabels | an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the observations identified according to id. If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified observations. Default is <code>getGroups(x)</code> . |
| grid     | an optional logical value indicating whether a grid should be added to plot. Default depends on the type of Trellis plot used: if <code>xyplot</code> defaults to <code>TRUE</code> , else defaults to <code>FALSE</code> .  |
| ...      | optional arguments passed to the Trellis plot function.  |

**Value**

a diagnostic Trellis plot.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

**Examples**

```
fm1 <- lmList(distance ~ age | Subject, Orthodont)
# standardized residuals versus fitted values by gender
plot(fm1, resid(., type = "pool") ~ fitted(.) | Sex, abline = 0, id = 0.05)
# box-plots of residuals by Subject
plot(fm1, Subject ~ resid(.))
# observed versus fitted values by Subject
plot(fm1, distance ~ fitted(.) | Subject, abline = c(0,1))
```

---

|                     |                                      |
|---------------------|--------------------------------------|
| plot.nffGroupedData | <i>Plot an nffGroupedData Object</i> |
|---------------------|--------------------------------------|

---

**Description**

A Trellis dot-plot of the response by group is generated. If outer variables are specified, the combination of their levels are used to determine the panels of the Trellis display. The Trellis function `dotplot` is used.

**Usage**

```
## S3 method for class 'nffGroupedData'
plot(x, outer, inner, innerGroups, xlab, ylab, strip, panel, key,
     grid, ...)
```

**Arguments**

|                          |  |
|--------------------------|--|
| <code>x</code>           | an object inheriting from class <code>nffGroupedData</code> , representing a <code>groupedData</code> object with a factor primary covariate and a single grouping level.  |
| <code>outer</code>       | an optional logical value or one-sided formula, indicating covariates that are outer to the grouping factor, which are used to determine the panels of the Trellis plot. If equal to <code>TRUE</code> , <code>attr(object, "outer")</code> is used to indicate the outer covariates. An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. Defaults to <code>NULL</code> , meaning that no outer covariates are to be used. |
| <code>inner</code>       | an optional logical value or one-sided formula, indicating a covariate that is inner to the grouping factor, which is used to associate points within each panel of the Trellis plot. If equal to <code>TRUE</code> , <code>attr(object, "inner")</code> is used to indicate the inner covariate. An inner covariate can change within the sets of rows defined by the grouping factor. Defaults to <code>NULL</code> , meaning that no inner covariate is present.  |
| <code>innerGroups</code> | an optional one-sided formula specifying a factor to be used for grouping the levels of the inner covariate. Different colors, or symbols, are used for each level of the <code>innerGroups</code> factor. Default is <code>NULL</code> , meaning that no <code>innerGroups</code> covariate is present.   |
| <code>xlab</code>        | an optional character string with the label for the horizontal axis. Default is the <code>y</code> elements of <code>attr(object, "labels")</code> and <code>attr(object, "units")</code> pasted together.   |
| <code>ylab</code>        | an optional character string with the label for the vertical axis. Default is the grouping factor name.  |
| <code>strip</code>       | an optional function passed as the <code>strip</code> argument to the <code>dotplot</code> function. Default is <code>strip.default(..., style = 1)</code> (see <code>trellis.args</code> ).   |
| <code>panel</code>       | an optional function used to generate the individual panels in the Trellis display, passed as the <code>panel</code> argument to the <code>dotplot</code> function.  |
| <code>key</code>         | an optional logical function or function. If <code>TRUE</code> and either <code>inner</code> or <code>innerGroups</code> are non- <code>NULL</code> , a legend for the different inner ( <code>innerGroups</code> ) levels is included at the top of the plot. If given as a function, it is passed as the <code>key</code> argument to the <code>dotplot</code> function. Default is <code>TRUE</code> if either <code>inner</code> or <code>innerGroups</code> are non- <code>NULL</code> and <code>FALSE</code> otherwise.  |
| <code>grid</code>        | this argument is included for consistency with the <code>plot.nfnGroupedData</code> method calling sequence. It is ignored in this method function.  |
| <code>...</code>         | optional arguments passed to the <code>dotplot</code> function.  |

**Value**

a Trellis dot-plot of the response by group.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

**Examples**

```
plot(Machines)
plot(Machines, inner = TRUE)
```

---

`plot.nfnGroupedData`     *Plot an nfnGroupedData Object*

---

**Description**

A Trellis plot of the response versus the primary covariate is generated. If outer variables are specified, the combination of their levels are used to determine the panels of the Trellis display. Otherwise, the levels of the grouping variable determine the panels. A scatter plot of the response versus the primary covariate is displayed in each panel, with observations corresponding to same inner group joined by line segments. The Trellis function `xyplot` is used.

**Usage**

```
## S3 method for class 'nfnGroupedData'
plot(x, outer, inner, innerGroups, xlab, ylab, strip, aspect, panel,
      key, grid, ...)
```

**Arguments**

|                          |  |
|--------------------------|--|
| <code>x</code>           | an object inheriting from class <code>nfnGroupedData</code> , representing a <code>groupedData</code> object with a numeric primary covariate and a single grouping level.   |
| <code>outer</code>       | an optional logical value or one-sided formula, indicating covariates that are outer to the grouping factor, which are used to determine the panels of the Trellis plot. If equal to <code>TRUE</code> , <code>attr(object, "outer")</code> is used to indicate the outer covariates. An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. Defaults to <code>NULL</code> , meaning that no outer covariates are to be used. |
| <code>inner</code>       | an optional logical value or one-sided formula, indicating a covariate that is inner to the grouping factor, which is used to associate points within each panel of the Trellis plot. If equal to <code>TRUE</code> , <code>attr(object, "inner")</code> is used to indicate the inner covariate. An inner covariate can change within the sets of rows defined by the grouping factor. Defaults to <code>NULL</code> , meaning that no inner covariate is present.  |
| <code>innerGroups</code> | an optional one-sided formula specifying a factor to be used for grouping the levels of the inner covariate. Different colors, or line types, are used for each level of the <code>innerGroups</code> factor. Default is <code>NULL</code> , meaning that no <code>innerGroups</code> covariate is present.  |
| <code>xlab, ylab</code>  | optional character strings with the labels for the plot. Default is the corresponding elements of <code>attr(object, "labels")</code> and <code>attr(object, "units")</code> pasted together.  |

|        |   |
|--------|---|
| strip  | an optional function passed as the strip argument to the xyplot function. Default is strip.default(..., style = 1) (see trellis.args).  |
| aspect | an optional character string indicating the aspect ratio for the plot passed as the aspect argument to the xyplot function. Default is "xy" (see trellis.args).   |
| panel  | an optional function used to generate the individual panels in the Trellis display, passed as the panel argument to the xyplot function.  |
| key    | an optional logical function or function. If TRUE and innerGroups is non-NULL, a legend for the different innerGroups levels is included at the top of the plot. If given as a function, it is passed as the key argument to the xyplot function. Default is TRUE if innerGroups is non-NULL and FALSE otherwise. |
| grid   | an optional logical value indicating whether a grid should be added to plot. Default is TRUE.   |
| ...    | optional arguments passed to the xyplot function.   |

**Value**

a Trellis plot of the response versus the primary covariate.

plot.nmGroupedData      *Plot an nmGroupedData Object*

---

**Description**

The groupedData object is summarized by the values of the displayLevel grouping factor (or the combination of its values and the values of the covariate indicated in preserve, if any is present). The collapsed data is used to produce a new groupedData object, with grouping factor given by the displayLevel factor, which is plotted using the appropriate plot method for groupedData objects with single level of grouping.

**Usage**

```
## S3 method for class 'nmGroupedData'
plot(x, collapseLevel, displayLevel, outer, inner,
     preserve, FUN, subset, key, grid, ...)
```

**Arguments**

- |               |  |
|---------------|--|
| x             | an object inheriting from class <code>nmGroupedData</code> , representing a <code>groupedData</code> object with multiple grouping factors.  |
| collapseLevel | an optional positive integer or character string indicating the grouping level to use when collapsing the data. Level values increase from outermost to innermost grouping. Default is the highest or innermost level of grouping.   |
| displayLevel  | an optional positive integer or character string indicating the grouping level to use for determining the panels in the Trellis display, when <code>outer</code> is missing. Default is <code>collapseLevel</code> .   |
| outer         | an optional logical value or one-sided formula, indicating covariates that are outer to the <code>displayLevel</code> grouping factor, which are used to determine the panels of the Trellis plot. If equal to <code>TRUE</code> , the <code>displayLevel</code> element <code>attr(object, "outer")</code> is used to indicate the outer covariates. An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. Defaults to <code>NULL</code> , meaning that no outer covariates are to be used.   |
| inner         | an optional logical value or one-sided formula, indicating a covariate that is inner to the <code>displayLevel</code> grouping factor, which is used to associate points within each panel of the Trellis plot. If equal to <code>TRUE</code> , <code>attr(object, "outer")</code> is used to indicate the inner covariate. An inner covariate can change within the sets of rows defined by the grouping factor. Defaults to <code>NULL</code> , meaning that no inner covariate is present.  |
| preserve      | an optional one-sided formula indicating a covariate whose levels should be preserved when collapsing the data according to the <code>collapseLevel</code> grouping factor. The collapsing factor is obtained by pasting together the levels of the <code>collapseLevel</code> grouping factor and the values of the covariate to be preserved. Default is <code>NULL</code> , meaning that no covariates need to be preserved.  |
| FUN           | an optional summary function or a list of summary functions to be used for collapsing the data. The function or functions are applied only to variables in object that vary within the groups defined by <code>collapseLevel</code> . Invariant variables are always summarized by group using the unique value that they assume within that group. If <code>FUN</code> is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If <code>FUN</code> is a list of functions, the names in the list should designate classes of variables in the data such as <code>ordered</code> , <code>factor</code> , or <code>numeric</code> . The indicated function will be applied to any non-invariant variables of that class. The default functions to be used are <code>mean</code> for numeric factors, and <code>Mode</code> for both <code>factor</code> and <code>ordered</code> . The <code>Mode</code> function, defined internally in <code>gsummary</code> , returns the modal or most popular value of the variable. It is different from the <code>mode</code> function that returns the S-language mode of the variable. |
| subset        | an optional named list. Names can be either positive integers representing grouping levels, or names of grouping factors. Each element in the list is a vector indicating the levels of the corresponding grouping factor to be used for plotting the data. Default is <code>NULL</code> , meaning that all levels are used.   |

|      |   |
|------|---|
| key  | an optional logical value, or list. If TRUE, a legend is included at the top of the plot indicating which symbols (colors) correspond to which prediction levels. If FALSE, no legend is included. If given as a list, key is passed down as an argument to the trellis function generating the plots (xyplot). Defaults to TRUE. |
| grid | an optional logical value indicating whether a grid should be added to plot. Default is TRUE.   |
| ...  | optional arguments passed to the Trellis plot function.   |

### Value

a Trellis display of the data collapsed over the values of the collapseLevel grouping factor and grouped according to the displayLevel grouping factor.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

|----------------|--------------------------------|

---

### Description

If form is missing, or is given as a one-sided formula, a Trellis dot-plot of the random effects is generated, with a different panel for each random effect (coefficient). Rows in the dot-plot are determined by the form argument (if not missing) or by the row names of the random effects (coefficients). If a single factor is specified in form, its levels determine the dot-plot rows (with possibly multiple dots per row); otherwise, if form specifies a crossing of factors, the dot-plot rows are determined by all combinations of the levels of the individual factors in the formula. The Trellis function dotplot is used in this method function.

If form is a two-sided formula, a Trellis display is generated, with a different panel for each variable listed in the right hand side of form. Scatter plots are generated for numeric variables and boxplots are generated for categorical (factor or ordered) variables.

**Usage**

```
## S3 method for class 'ranef.lme'
plot(x, form, omitFixed, level, grid, control, ...)
```

**Arguments**

|                        |  |
|------------------------|--|
| <code>x</code>         | an object inheriting from class " <code>ranef.lme</code> ", representing the estimated coefficients or estimated random effects for the <code>lme</code> object from which it was produced.  |
| <code>form</code>      | an optional formula specifying the desired type of plot. If given as a one-sided formula, a dotplot of the estimated random effects (coefficients) grouped according to all combinations of the levels of the factors named in <code>form</code> is returned. Single factors ( <code>~g</code> ) or crossed factors ( <code>~g1*g2</code> ) are allowed. If given as a two-sided formula, the left hand side must be a single random effects (coefficient) and the right hand side is formed by covariates in <code>x</code> separated by <code>+</code> . A Trellis display of the random effect (coefficient) versus the named covariates is returned in this case. Default is <code>NULL</code> , in which case the row names of the random effects (coefficients) are used.  |
| <code>omitFixed</code> | an optional logical value indicating whether columns with values that are constant across groups should be omitted. Default is <code>TRUE</code> .   |
| <code>level</code>     | an optional integer value giving the level of grouping to be used for <code>x</code> . Only used when <code>x</code> is a list with different components for each grouping level. Defaults to the highest or innermost level of grouping.  |
| <code>grid</code>      | an optional logical value indicating whether a grid should be added to plot. Only applies to plots associated with two-sided formulas in <code>form</code> . Default is <code>FALSE</code> .   |
| <code>control</code>   | an optional list with control values for the plot, when <code>form</code> is given as a two-sided formula. The control values are referenced by name in the <code>control</code> list and only the ones to be modified from the default need to be specified. Available values include: <code>drawLine</code> , a logical value indicating whether a loess smoother should be added to the scatter plots and a line connecting the medians should be added to the boxplots (default is <code>TRUE</code> ); <code>span.loess</code> , used as the <code>span</code> argument in the call to <code>panel.loess</code> (default is <code>2/3</code> ); <code>degree.loess</code> , used as the <code>degree</code> argument in the call to <code>panel.loess</code> (default is <code>1</code> ); <code>cex.axis</code> , the character expansion factor for the x-axis (default is <code>0.8</code> ); <code>srt.axis</code> , the rotation factor for the x-axis (default is <code>0</code> ); and <code>mgp.axis</code> , the margin parameters for the x-axis (default is <code>c(2, 0.5, 0)</code> ). |
| <code>...</code>       | optional arguments passed to the Trellis <code>dotplot</code> function.  |

**Value**

a Trellis plot of the estimated random-effects (coefficients) versus covariates, or groups.

## Description

If form is missing, or is given as a one-sided formula, a Trellis dot-plot of the random effects is generated, with a different panel for each random effect (coefficient). Rows in the dot-plot are determined by the form argument (if not missing) or by the row names of the random effects (coefficients). If a single factor is specified in form, its levels determine the dot-plot rows (with possibly multiple dots per row); otherwise, if form specifies a crossing of factors, the dot-plot rows are determined by all combinations of the levels of the individual factors in the formula. The Trellis function dotplot is used in this method function.

If form is a two-sided formula, a Trellis display is generated, with a different panel for each variable listed in the right hand side of form. Scatter plots are generated for numeric variables and boxplots are generated for categorical (factor or ordered) variables.

## Usage

```
## S3 method for class 'ranef.lmList'
plot(x, form, grid, control, ...)
```

## Arguments

- |         |   |
|---------|---|
| x       | an object inheriting from class " <b>ranef.lmList</b> ", representing the estimated coefficients or estimated random effects for the lmList object from which it was produced.  |
| form    | an optional formula specifying the desired type of plot. If given as a one-sided formula, a dotplot of the estimated random effects (coefficients) grouped according to all combinations of the levels of the factors named in form is returned. Single factors (~g) or crossed factors (~g1*g2) are allowed. If given as a two-sided formula, the left hand side must be a single random effects (coefficient) and the right hand side is formed by covariates in x separated by +. A Trellis display of the random effect (coefficient) versus the named covariates is returned in this case. Default is NULL, in which case the row names of the random effects (coefficients) are used. |
| grid    | an optional logical value indicating whether a grid should be added to plot. Only applies to plots associated with two-sided formulas in form. Default is FALSE.  |
| control | an optional list with control values for the plot, when form is given as a two-sided formula. The control values are referenced by name in the control list and only the ones to be modified from the default need to be specified. Available   |

values include: `drawLine`, a logical value indicating whether a loess smoother should be added to the scatter plots and a line connecting the medians should be added to the boxplots (default is `TRUE`); `span.loess`, used as the `span` argument in the call to `panel.loess` (default is `2/3`); `degree.loess`, used as the `degree` argument in the call to `panel.loess` (default is `1`); `cex.axis`, the character expansion factor for the x-axis (default is `0.8`); `srt.axis`, the rotation factor for the x-axis (default is `0`); and `mgp.axis`, the margin parameters for the x-axis (default is `c(2, 0.5, 0)`).

... optional arguments passed to the Trellis `dotplot` function.

### Value

a Trellis plot of the estimated random-effects (coefficients) versus covariates, or groups.

fm1RE <- ranef(fm1, aug = TRUE)
plot(fm1RE, form = ~ Sex)
## Not run: plot(fm1RE, form = age ~ Sex)
```

---

plot.Variogram

*Plot a Variogram Object*

---

### Description

an xyplot of the semi-variogram versus the distances is produced. If `smooth = TRUE`, a loess smoother is added to the plot. If `showModel = TRUE` and `x` includes an "modelVariog" attribute, the corresponding semi-variogram is added to the plot.

### Usage

```
## S3 method for class 'Variogram'
plot(x, smooth, showModel, sigma, span, xlab,
     ylab, type, ylim, grid, ...)
```

### Arguments

|                     |  |
|---------------------|--|
| <code>x</code>      | an object inheriting from class " <a href="#">Variogram</a> ", consisting of a data frame with two columns named <code>variog</code> and <code>dist</code> , representing the semi-variogram values and the corresponding distances. |
| <code>smooth</code> | an optional logical value controlling whether a loess smoother should be added to the plot. Defaults to <code>TRUE</code> , when <code>showModel</code> is <code>FALSE</code> .  |

|           |   |
|-----------|---|
| showModel | an optional logical value controlling whether the semi-variogram corresponding to an "modelVariog" attribute of x, if any is present, should be added to the plot. Defaults to TRUE, when the "modelVariog" attribute is present. |
| sigma     | an optional numeric value used as the height of a horizontal line displayed in the plot. Can be used to represent the process standard deviation. Default is NULL, implying that no horizontal line is drawn.                     |
| span      | an optional numeric value with the smoothing parameter for the loess fit. Default is 0.6.   |
| xlab,ylab | optional character strings with the x- and y-axis labels. Default respectively to "Distance" and "SemiVariogram".   |
| type      | an optional character indicating the type of plot. Defaults to "p".   |
| ylim      | an optional numeric vector with the limits for the y-axis. Defaults to <code>c(0, max(x\$variog))</code> .  |
| grid      | an optional logical value indicating whether a grid should be added to plot. Default is FALSE.  |
| ...       | optional arguments passed to the Trellis <code>xyplot</code> function.  |

**Value**

an `xyplot` Trellis plot.

```

---

pooledSD

*Extract Pooled Standard Deviation*

---

**Description**

The pooled estimated standard deviation is obtained by adding together the residual sum of squares for each non-null element of object, dividing by the sum of the corresponding residual degrees-of-freedom, and taking the square-root.

**Usage**

```
pooledSD(object)
```

**Arguments**

object            an object inheriting from class `lmList`.

**Value**

the pooled standard deviation for the non-null elements of object, with an attribute df with the number of degrees-of-freedom used in the estimation.

predict(fm1, newSoybean)
```

predict.lme

*Predictions from an lme Object***Description**

The predictions at level  $i$  are obtained by adding together the population predictions (based only on the fixed effects estimates) and the estimated contributions of the random effects to the predictions at grouping levels less or equal to  $i$ . The resulting values estimate the best linear unbiased predictions (BLUPs) at level  $i$ . If group values not included in the original grouping factors are present in newdata, the corresponding predictions will be set to NA for levels greater or equal to the level at which the unknown groups occur.

**Usage**

```
## S3 method for class 'lme'
predict(object, newdata, level = 0, asList = FALSE,
        na.action = na.fail, ...)
```

**Arguments**

|           |  |
|-----------|--|
| object    | an object inheriting from class " <b>lme</b> ", representing a fitted linear mixed-effects model.  |
| newdata   | an optional data frame to be used for obtaining the predictions. All variables used in the fixed and random effects models, as well as the grouping factors, must be present in the data frame. If missing, the fitted values are returned.  |
| level     | an optional integer vector giving the level(s) of grouping to be used in obtaining the predictions. Level values increase from outermost to innermost grouping, with level zero corresponding to the population predictions. Defaults to the highest or innermost level of grouping. |
| asList    | an optional logical value. If TRUE and a single value is given in level, the returned object is a list with the predictions split by groups; else the returned value is either a vector or a data frame, according to the length of level.   |
| na.action | a function that indicates what should happen when newdata contains NAs. The default action (na.fail) causes the function to print an error message and terminate if there are any incomplete observations.   |
| ...       | some methods for this generic require additional arguments. None are used in this method.  |

**Value**

if a single level of grouping is specified in level, the returned value is either a list with the predictions split by groups (asList = TRUE) or a vector with the predictions (asList = FALSE); else, when multiple grouping levels are specified in level, the returned object is a data frame with columns given by the predictions at different levels and the grouping factors.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[lme](#), [fitted.lme](#)

**Examples**

```
fm1 <- lme(distance ~ age, Orthodont, random = ~ age | Subject)
newOrth <- data.frame(Sex = c("Male", "Male", "Female", "Female", "Male", "Male"),
                     age = c(15, 20, 10, 12, 2, 4),
                     Subject = c("M01", "M01", "F30", "F30", "M04", "M04"))
## The 'Orthodont' data has *no* 'F30', so predict NA at level 1 :
predict(fm1, newOrth, level = 0:1)
```

---

predict.lmList

*Predictions from an lmList Object*

---

**Description**

If the grouping factor corresponding to object is included in newdata, the data frame is partitioned according to the grouping factor levels; else, newdata is repeated for all lm components. The predictions and, optionally, the standard errors for the predictions, are obtained for each lm component of object, using the corresponding element of the partitioned newdata, and arranged into a list with as many components as object, or combined into a single vector or data frame (if se.fit=TRUE).

**Usage**

```
## S3 method for class 'lmList'
predict(object, newdata, subset, pool, asList, se.fit, ...)
```

**Arguments**

|         |  |
|---------|--|
| object  | an object inheriting from class " <a href="#">lmList</a> ", representing a list of lm objects with a common model.   |
| newdata | an optional data frame to be used for obtaining the predictions. All variables used in the object model formula must be present in the data frame. If missing, the same data frame used to produce object is used. |
| subset  | an optional character or integer vector naming the lm components of object from which the predictions are to be extracted. Default is NULL, in which case all components are used.                                 |
| asList  | an optional logical value. If TRUE, the returned object is a list with the predictions split by groups; else the returned value is a vector. Defaults to FALSE.  |
| pool    | an optional logical value indicating whether a pooled estimate of the residual standard error should be used. Default is attr(object, "pool").   |
| se.fit  | an optional logical value indicating whether pointwise standard errors should be computed along with the predictions. Default is FALSE.  |
| ...     | some methods for this generic require additional arguments. None are used in this method.  |

**Value**

a list with components given by the predictions (and, optionally, the standard errors for the predictions) from each `lm` component of `object`, a vector with the predictions from all `lm` components of `object`, or a data frame with columns given by the predictions and their corresponding standard errors.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[lmList](#), [predict.lm](#)

**Examples**

```
fm1 <- lmList(distance ~ age | Subject, Orthodont)
predict(fm1, se.fit = TRUE)
```

---

predict.nlme

*Predictions from an nlme Object*

---

**Description**

The predictions at level  $i$  are obtained by adding together the contributions from the estimated fixed effects and the estimated random effects at levels less or equal to  $i$  and evaluating the model function at the resulting estimated parameters. If group values not included in the original grouping factors are present in `newdata`, the corresponding predictions will be set to NA for levels greater or equal to the level at which the unknown groups occur.

**Usage**

```
## S3 method for class 'nlme'
predict(object, newdata, level = 0, asList = FALSE,
        na.action = na.fail, naPattern = NULL, ...)
```

**Arguments**

|                      |  |
|----------------------|--|
| <code>object</code>  | an object inheriting from class " <code>nlme</code> ", representing a fitted nonlinear mixed-effects model.  |
| <code>newdata</code> | an optional data frame to be used for obtaining the predictions. All variables used in the nonlinear model, the fixed and the random effects models, as well as the grouping factors, must be present in the data frame. If missing, the fitted values are returned.   |
| <code>level</code>   | an optional integer vector giving the level(s) of grouping to be used in obtaining the predictions. Level values increase from outermost to innermost grouping, with level zero corresponding to the population predictions. Defaults to the highest or innermost level of grouping (and is <code>object\$dim\$Q</code> ). |
| <code>asList</code>  | an optional logical value. If TRUE and a single value is given in <code>level</code> , the returned object is a list with the predictions split by groups; else the returned value is either a vector or a data frame, according to the length of <code>level</code> .   |

|           |  |
|-----------|--|
| na.action | a function that indicates what should happen when newdata contains NAs. The default action (na.fail) causes the function to print an error message and terminate if there are any incomplete observations. |
| naPattern | an expression or formula object, specifying which returned values are to be regarded as missing.   |
| ...       | some methods for this generic require additional arguments. None are used in this method.  |

### Value

if a single level of grouping is specified in `level`, the returned value is either a list with the predictions split by groups (`asList = TRUE`) or a vector with the predictions (`asList = FALSE`); else, when multiple grouping levels are specified in `level`, the returned object is a data frame with columns given by the predictions at different levels and the grouping factors.

newLL.301 <- data.frame(age = age., Seed = 301)
newLL.329 <- data.frame(age = age., Seed = 329)
(p301 <- predict(fm1, newLL.301, level = 0:1))
(p329 <- predict(fm1, newLL.329, level = 0:1))
## Prediction are the same at level 0 :
all.equal(p301[, "predict.fixed"],
          p329[, "predict.fixed"])
## and differ by the 'Seed' effect at level 1 :
p301[, "predict.Seed"] -
p329[, "predict.Seed"]
```

---

```
print.summary.pdMat
```

*Print a summary.pdMat Object*

---

## Description

The standard deviations and correlations associated with the positive-definite matrix represented by object (considered as a variance-covariance matrix) are printed, together with the formula and the grouping level associated object, if any are present.

## Usage

```
## S3 method for class 'summary.pdMat'
print(x, sigma, rdig, Level, resid, ...)
```

## Arguments

|                    |  |
|--------------------|--|
| <code>x</code>     | an object inheriting from class " <a href="#">summary.pdMat</a> ", generally resulting from applying <a href="#">summary</a> to an object inheriting from class " <a href="#">pdMat</a> ".   |
| <code>sigma</code> | an optional numeric value used as a multiplier for the square-root factor of the positive-definite matrix represented by object (usually the estimated within-group standard deviation from a mixed-effects model). Defaults to 1. |
| <code>rdig</code>  | an optional integer value with the number of significant digits to be used in printing correlations. Defaults to 3.  |
| <code>Level</code> | an optional character string with a description of the grouping level associated with object (generally corresponding to levels of grouping in a mixed-effects model). Defaults to NULL.   |
| <code>resid</code> | an optional logical value. If TRUE an extra row with the "residual" standard deviation given in sigma will be included in the output. Defaults to FALSE.   |
| <code>...</code>   | optional arguments passed to <code>print.default</code> ; see the documentation on that method function.   |

|---------------|-------------------------------|
| print.varFunc | <i>Print a varFunc Object</i> |
|---------------|-------------------------------|

---

### Description

The class and the coefficients associated with x are printed.

### Usage

```
## S3 method for class 'varFunc'
print(x, ...)
```

### Arguments

|     |  |
|-----|--|
| x   | an object inheriting from class " <a href="#">varFunc</a> ", representing a variance function structure. |
| ... | optional arguments passed to print.default; see the documentation on that method function.               |

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

[summary.varFunc](#)

### Examples

```
vf1 <- varPower(0.3, form = ~age)
vf1 <- Initialize(vf1, Orthodont)
print(vf1)
```

---

|            |   |
|------------|---|
| qqnorm.gls | <i>Normal Plot of Residuals from a gls Object</i> |
|------------|---|

---

### Description

Diagnostic plots for assessing the normality of residuals the generalized least squares fit are obtained. The form argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a | operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display.

### Usage

```
## S3 method for class 'gls'
qqnorm(y, form, abline, id, idLabels, grid, ...)
```

**Arguments**

|                       |   |
|-----------------------|---|
| <code>y</code>        | an object inheriting from class " <code>gls</code> ", representing a generalized least squares fitted model.  |
| <code>form</code>     | an optional one-sided formula specifying the desired type of plot. Any variable present in the original data frame used to obtain <code>y</code> can be referenced. In addition, <code>y</code> itself can be referenced in the formula using the symbol <code>"."</code> . Conditional expressions on the right of a <code> </code> operator can be used to define separate panels in a Trellis display. The expression on the right hand side of <code>form</code> and to the left of a <code> </code> operator must evaluate to a residuals vector. Default is <code>~ resid(., type = "p")</code> , corresponding to a normal plot of the standardized residuals. |
| <code>abline</code>   | an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.  |
| <code>id</code>       | an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized residuals (random effects). Observations with absolute standardized residuals (random effects) greater than the $1 - \text{value}/2$ quantile of the standard normal distribution are identified in the plot using <code>idLabels</code> . If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified.   |
| <code>idLabels</code> | an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the observations identified according to <code>id</code> . If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified observations. Default is the innermost grouping factor.   |
| <code>grid</code>     | an optional logical value indicating whether a grid should be added to plot. Default depends on the type of Trellis plot used: if <code>xypLOT</code> defaults to <code>TRUE</code> , else defaults to <code>FALSE</code> .   |
| <code>...</code>      | optional arguments passed to the Trellis plot function.   |

**Value**

a diagnostic Trellis plot for assessing normality of residuals.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

qqnorm(fm1, abline = c(0,1))
```

qqnorm.lme

*Normal Plot of Residuals or Random Effects from an lme Object***Description**

Diagnostic plots for assessing the normality of residuals and random effects in the linear mixed-effects fit are obtained. The `form` argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a `|` operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display.

**Usage**

```
## S3 method for class 'lme'
qqnorm(y, form, abline, id, idLabels, grid, ...)
```

**Arguments**

- |                       |   |
|-----------------------|---|
| <code>y</code>        | an object inheriting from class <code>"lme"</code> , representing a fitted linear mixed-effects model or from class <code>"lmList"</code> , representing a list of <code>lm</code> objects, or from class <code>"lm"</code> , representing a fitted linear model, or from class <code>"nls"</code> , representing a nonlinear least squares fitted model.   |
| <code>form</code>     | an optional one-sided formula specifying the desired type of plot. Any variable present in the original data frame used to obtain <code>y</code> can be referenced. In addition, <code>y</code> itself can be referenced in the formula using the symbol <code>"."</code> . Conditional expressions on the right of a <code> </code> operator can be used to define separate panels in a Trellis display. The expression on the right hand side of <code>form</code> and to the left of a <code> </code> operator must evaluate to a residuals vector, or a random effects matrix. Default is <code>~ resid(., type = "p")</code> , corresponding to a normal plot of the standardized residuals evaluated at the innermost level of nesting. |
| <code>abline</code>   | an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.  |
| <code>id</code>       | an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized residuals (random effects). Observations with absolute standardized residuals (random effects) greater than the $1 - \text{value}/2$ quantile of the standard normal distribution are identified in the plot using <code>idLabels</code> . If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified.   |
| <code>idLabels</code> | an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the observations identified according to <code>id</code> . If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified observations. Default is the innermost grouping factor.   |
| <code>grid</code>     | an optional logical value indicating whether a grid should be added to plot. Default is <code>FALSE</code> .  |
| <code>...</code>      | optional arguments passed to the Trellis plot function.   |

**Value**

a diagnostic Trellis plot for assessing normality of residuals or random effects.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

fm1 <- lme(distance ~ age, Orthodont, random = ~ age | Subject)
## normal plot of standardized residuals by gender
qqnorm(fm1, ~ resid(., type = "p") | Sex, abline = c(0, 1))
## normal plots of random effects
qqnorm(fm1, ~ranef(.))
```

---

Quinidine

*Quinidine Kinetics*

---

**Description**

The Quinidine data frame has 1471 rows and 14 columns.

**Format**

This data frame contains the following columns:

**Subject** a factor identifying the patient on whom the data were collected.

**time** a numeric vector giving the time (hr) at which the drug was administered or the blood sample drawn. This is measured from the time the patient entered the study.

**conc** a numeric vector giving the serum quinidine concentration (mg/L).

**dose** a numeric vector giving the dose of drug administered (mg). Although there were two different forms of quinidine administered, the doses were adjusted for differences in salt content by conversion to milligrams of quinidine base.

**interval** a numeric vector giving the when the drug has been given at regular intervals for a sufficiently long period of time to assume steady state behavior, the interval is recorded.

**Age** a numeric vector giving the age of the subject on entry to the study (yr).

**Height** a numeric vector giving the height of the subject on entry to the study (in.).

**Weight** a numeric vector giving the body weight of the subject (kg).

**Race** a factor with levels Caucasian, Latin, and Black identifying the race of the subject.

**Smoke** a factor with levels no and yes giving smoking status at the time of the measurement.

**Ethanol** a factor with levels none, current, former giving ethanol (alcohol) abuse status at the time of the measurement.

**Heart** a factor with levels No/Mild, Moderate, and Severe indicating congestive heart failure for the subject.

**Creatinine** an ordered factor with levels < 50 <=> 50 indicating the creatine clearance (mg/min).

**glyco** a numeric vector giving the alpha-1 acid glycoprotein concentration (mg/dL). Often measured at the same time as the quinidine concentration.

## Details

Verme et al. (1992) analyze routine clinical data on patients receiving the drug quinidine as a treatment for cardiac arrhythmia (atrial fibrillation of ventricular arrhythmias). All patients were receiving oral quinidine doses. At irregular intervals blood samples were drawn and serum concentrations of quinidine were determined. These data are analyzed in several publications, including Davidian and Giltinan (1995, section 9.3).

---

|           |  |
|-----------|--|
| quinModel | <i>Model function for the Quinidine data</i> |
|-----------|--|

---

## Description

A model function for a model used with the Quinidine data. This function calls compiled C code.

## Usage

```
quinModel(Subject, time, conc, dose, interval, lV, lKa, lCl)
```

## Arguments

|          |   |
|----------|---|
| Subject  | a factor identifying the patient on whom the data were collected.   |
| time     | a numeric vector giving the time (hr) at which the drug was administered or the blood sample drawn. This is measured from the time the patient entered the study.   |
| conc     | a numeric vector giving the serum quinidine concentration (mg/L).   |
| dose     | a numeric vector giving the dose of drug administered (mg). Although there were two different forms of quinidine administered, the doses were adjusted for differences in salt content by conversion to milligrams of quinidine base. |
| interval | a numeric vector giving the when the drug has been given at regular intervals for a sufficiently long period of time to assume steady state behavior, the interval is recorded.   |
| lV       | numeric. A vector of values of the natural log of the effective volume of distribution according to Subject and time.   |
| lKa      | numeric. A vector of values of the natural log of the absorption rate constant according to Subject and time.   |
| lCl      | numeric. A vector of values of the natural log of the clearance parameter according to Subject and time.  |

**Details**

See the details section of [Quinidine](#) for a description of the model function that `quinModel` evaluates.

**Value**

a numeric vector of predicted quinidine concentrations.

Rail

---

*Evaluation of Stress in Railway Rails*

---

**Description**

The `Rail` data frame has 18 rows and 2 columns.

**Format**

This data frame contains the following columns:

**Rail** an ordered factor identifying the rail on which the measurement was made.

**travel** a numeric vector giving the travel time for ultrasonic head-waves in the rail (nanoseconds).  
The value given is the original travel time minus 36,100 nanoseconds.

**Details**

Devore (2000, Example 10.10, p. 427) cites data from an article in *Materials Evaluation* on “a study of travel time for a certain type of wave that results from longitudinal stress of rails used for railroad track.”

|----------------|-------------------------------|
| random.effects | <i>Extract Random Effects</i> |
|----------------|-------------------------------|

---

### Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `lmList` and `lme`.

### Usage

```
random.effects(object, ...)
ranef(object, ...)
```

### Arguments

|                     |   |
|---------------------|---|
| <code>object</code> | any fitted model object from which random effects estimates can be extracted. |
| <code>...</code>    | some methods for this generic function require additional arguments.          |

### Value

will depend on the method function used; see the appropriate documentation.

### References

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer, esp. pp. 100, 461.

### See Also

[ranef.lmList](#), [ranef.lme](#)

### Examples

```
## see the method function documentation
```

---

|           |                                   |
|-----------|-----------------------------------|
| ranef.lme | <i>Extract lme Random Effects</i> |
|-----------|-----------------------------------|

---

### Description

The estimated random effects at level  $i$  are represented as a data frame with rows given by the different groups at that level and columns given by the random effects. If a single level of grouping is specified, the returned object is a data frame; else, the returned object is a list of such data frames. Optionally, the returned data frame(s) may be augmented with covariates summarized over groups.

### Usage

```
## S3 method for class 'lme'
ranef(object, augFrame, level, data, which, FUN,
       standard, omitGroupingFactor, subset, ...)
```

**Arguments**

|                    |   |
|--------------------|---|
| object             | an object inheriting from class " <code>lme</code> ", representing a fitted linear mixed-effects model.   |
| augFrame           | an optional logical value. If <code>TRUE</code> , the returned data frame is augmented with variables defined in <code>data</code> ; else, if <code>FALSE</code> , only the coefficients are returned. Defaults to <code>FALSE</code> .   |
| level              | an optional vector of positive integers giving the levels of grouping to be used in extracting the random effects from an object with multiple nested grouping levels. Defaults to all levels of grouping.  |
| data               | an optional data frame with the variables to be used for augmenting the returned data frame when <code>augFrame = TRUE</code> . Defaults to the data frame used to fit object.  |
| which              | an optional positive integer vector specifying which columns of data should be used in the augmentation of the returned data frame. Defaults to all columns in data.  |
| FUN                | an optional summary function or a list of summary functions to be applied to group-varying variables, when collapsing data by groups. Group-invariant variables are always summarized by the unique value that they assume within that group. If FUN is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If FUN is a list of functions, the names in the list should designate classes of variables in the frame such as <code>ordered</code> , <code>factor</code> , or <code>numeric</code> . The indicated function will be applied to any group-varying variables of that class. The default functions to be used are <code>mean</code> for numeric factors, and <code>Mode</code> for both <code>factor</code> and <code>ordered</code> . The <code>Mode</code> function, defined internally in <code>gsummary</code> , returns the modal or most popular value of the variable. It is different from the <code>mode</code> function that returns the S-language mode of the variable. |
| standard           | an optional logical value indicating whether the estimated random effects should be "standardized" (i.e. divided by the estimate of the standard deviation of that group of random effects). Defaults to <code>FALSE</code> .   |
| omitGroupingFactor | an optional logical value. When <code>TRUE</code> the grouping factor itself will be omitted from the group-wise summary of data but the levels of the grouping factor will continue to be used as the row names for the returned data frame. Defaults to <code>FALSE</code> .  |
| subset             | an optional expression indicating for which rows the random effects should be extracted.  |
| ...                | some methods for this generic require additional arguments. None are used in this method.   |

**Value**

a data frame, or list of data frames, with the estimated random effects at the grouping level(s) specified in `level` and, optionally, other covariates summarized over groups. The returned object inherits from classes `random.effects.lme` and `data.frame`.

**Author(s)**

Description

The difference between the individual lm components coefficients and their average is calculated.

Usage

```
## S3 method for class 'lmList'
ranef(object, augFrame, data, which, FUN, standard,
       omitGroupingFactor, ...)
```

Arguments

|          |  |
|----------|--|
| object   | an object inheriting from class " <a href="#">lmList</a> ", representing a list of lm objects with a common model.   |
| augFrame | an optional logical value. If TRUE, the returned data frame is augmented with variables defined in data; else, if FALSE, only the coefficients are returned. Defaults to FALSE.  |
| data     | an optional data frame with the variables to be used for augmenting the returned data frame when augFrame = TRUE. Defaults to the data frame used to fit object.   |
| which    | an optional positive integer vector specifying which columns of data should be used in the augmentation of the returned data frame. Defaults to all columns in data.   |
| FUN      | an optional summary function or a list of summary functions to be applied to group-varying variables, when collapsing data by groups. Group-invariant variables are always summarized by the unique value that they assume within that group. If FUN is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If FUN is a list of functions, the names in the list should designate classes of variables in the frame such as ordered, factor, or numeric. The indicated function will be applied to any group-varying variables of that class. The default functions to be used are mean for numeric factors, and Mode for both factor and ordered. The Mode function, |

|                    |   |
|--------------------|---|
|                    | defined internally in gsummary, returns the modal or most popular value of the variable. It is different from the mode function that returns the S-language mode of the variable.   |
| standard           | an optional logical value indicating whether the estimated random effects should be "standardized" (i.e. divided by the corresponding estimated standard error). Defaults to FALSE.   |
| omitGroupingFactor | an optional logical value. When TRUE the grouping factor itself will be omitted from the group-wise summary of data but the levels of the grouping factor will continue to be used as the row names for the returned data frame. Defaults to FALSE. |
| ...                | some methods for this generic require additional arguments. None are used in this method.   |

Value

a vector with the differences between the individual lm coefficients in object and their average.

recalc

---

*Recalculate Condensed Linear Model Object*

---

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `corStruct`, `modelStruct`, `reStruct`, and `varFunc`.

**Usage**

```
recalc(object, conLin, ...)
```

**Arguments**

|                     |  |
|---------------------|--|
| <code>object</code> | any object which induces a recalculation of the condensed linear model object <code>conLin</code> .  |
| <code>conLin</code> | a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model. |
| <code>...</code>    | some methods for this generic can take additional arguments.   |

**Value**

the recalculated condensed linear model object.

**Note**

This function is only used inside model fitting functions, such as `lme` and `gls`, that require recalculation of a condensed linear model object.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

---

|                  |   |
|------------------|---|
| recalc.corStruct | <i>Recalculate for corStruct Object</i> |
|------------------|---|

---

### Description

This method function pre-multiplies the "Xy" component of conLin by the transpose square-root factor(s) of the correlation matrix (matrices) associated with object and adds the log-likelihood contribution of object, given by logLik(object), to the "logLik" component of conLin.

### Usage

```
## S3 method for class 'corStruct'  
recalc(object, conLin, ...)
```

### Arguments

|        |  |
|--------|--|
| object | an object inheriting from class " <a href="#">corStruct</a> ", representing a correlation structure.   |
| conLin | a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model. |
| ...    | some methods for this generic require additional arguments. None are used in this method.  |

### Value

the recalculated condensed linear model object.

### Note

This method function is only used inside model fitting functions, such as lme and gls, that allow correlated error terms.

|                    |   |
|--------------------|---|
| recalc.modelStruct | <i>Recalculate for a modelStruct Object</i> |
|--------------------|---|

---

### Description

This method function recalculates the condensed linear model object using each element of object sequentially from last to first.

### Usage

```
## S3 method for class 'modelStruct'  
recalc(object, conLin, ...)
```

### Arguments

|        |  |
|--------|--|
| object | an object inheriting from class "modelStruct", representing a list of model components, such as corStruct and varFunc objects.   |
| conLin | an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model. Defaults to attr(object, "conLin"). |
| ...    | some methods for this generic require additional arguments. None are used in this method.  |

### Value

the recalculated condensed linear model object.

### Note

This method function is generally only used inside model fitting functions, such as lme and gls, that allow model components, such as correlated error terms and variance functions.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

[recalc.corStruct](#), [recalc.reStruct](#), [recalc.varFunc](#)

---

recalc.reStruct

*Recalculate for an reStruct Object*

---

### Description

The log-likelihood, or restricted log-likelihood, of the Gaussian linear mixed-effects model represented by object and conLin (assuming spherical within-group covariance structure), evaluated at coef(object) is calculated and added to the logLik component of conLin. The settings attribute of object determines whether the log-likelihood, or the restricted log-likelihood, is to be calculated. The computational methods for the (restricted) log-likelihood calculations are described in Bates and Pinheiro (1998).

### Usage

```
## S3 method for class 'reStruct'
recalc(object, conLin, ...)
```

### Arguments

|        |  |
|--------|--|
| object | an object inheriting from class " <a href="#">reStruct</a> ", representing a random effects structure and consisting of a list of pdMat objects.   |
| conLin | a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model. |
| ...    | some methods for this generic require additional arguments. None are used in this method.  |

### Value

the condensed linear model with its logLik component updated.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

[logLik](#), [lme](#), [recalc](#), [reStruct](#)

---

recalc.varFunc

*Recalculate for varFunc Object*

---

### Description

This method function pre-multiplies the "Xy" component of conLin by a diagonal matrix with diagonal elements given by the weights corresponding to the variance structure represented by objecte and adds the log-likelihood contribution of object, given by logLik(object), to the "logLik" component of conLin.

Usage

```
## S3 method for class 'varFunc'  
recalc(object, conLin, ...)
```

Arguments

|        |  |
|--------|--|
| object | an object inheriting from class "varFunc", representing a variance function structure.   |
| conLin | a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model. |
| ...    | some methods for this generic require additional arguments. None are used in this method.  |

Value

the recalculated condensed linear model object.

Note

This method function is only used inside model fitting functions, such as lme and gls, that allow heteroscedastic error terms.

residuals.gls*Extract gls Residuals*

---

**Description**

The residuals for the linear model represented by object are extracted.

**Usage**

```
## S3 method for class 'gls'  
residuals(object, type, ...)
```

**Arguments**

|        |   |
|--------|---|
| object | an object inheriting from class " <a href="#">glS</a> ", representing a generalized least squares fitted linear model, or from class gnls, representing a generalized nonlinear least squares fitted linear model.  |
| type   | an optional character string specifying the type of residuals to be used. If "response", the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "response". |
| ...    | some methods for this generic function require additional arguments. None are used in this method.  |

**Value**

a vector with the residuals for the linear model represented by object.

---

|                            |                              |
|----------------------------|------------------------------|
| <code>residuals.lme</code> | <i>Extract lme Residuals</i> |
|----------------------------|------------------------------|

---

**Description**

The residuals at level  $i$  are obtained by subtracting the fitted levels at that level from the response vector (and dividing by the estimated within-group standard error, if `type="pearson"`). The fitted values at level  $i$  are obtained by adding together the population fitted values (based only on the fixed effects estimates) and the estimated contributions of the random effects to the fitted values at grouping levels less or equal to  $i$ .

**Usage**

```
## S3 method for class 'lme'
residuals(object, level = 0,
          type = c("response", "pearson", "normalized"), asList = FALSE, ...)
```

**Arguments**

|                     |  |
|---------------------|--|
| <code>object</code> | an object inheriting from class " <a href="#">lme</a> ", representing a fitted linear mixed-effects model.   |
| <code>level</code>  | an optional integer vector giving the level(s) of grouping to be used in extracting the residuals from <code>object</code> . Level values increase from outermost to innermost grouping, with level zero corresponding to the population residuals. Defaults to the highest or innermost level of grouping.  |
| <code>type</code>   | an optional character string specifying the type of residuals to be used. If "response", as by default, the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. |
| <code>asList</code> | an optional logical value. If TRUE and a single value is given in <code>level</code> , the returned object is a list with the residuals split by groups; else the returned value is either a vector or a data frame, according to the length of <code>level</code> . Defaults to FALSE.  |
| <code>...</code>    | some methods for this generic require additional arguments. None are used in this method.  |

**Value**

if a single level of grouping is specified in `level`, the returned value is either a list with the residuals split by groups (`asList = TRUE`) or a vector with the residuals (`asList = FALSE`); else, when multiple grouping levels are specified in `level`, the returned object is a data frame with columns given by the residuals at different levels and the grouping factors. For a vector or data frame result the `naresid` method is applied.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

[lme](#), [fitted.lme](#)

**Examples**

```
fm1 <- lme(distance ~ age + Sex, data = Orthodont, random = ~ 1)
head(residuals(fm1, level = 0:1))
summary(residuals(fm1) /
        residuals(fm1, type = "p")) # constant scaling factor 1.432
```

---

`residuals.lmeStruct`     *Calculate lmeStruct Residuals*

---

**Description**

The residuals at level  $i$  are obtained by subtracting the fitted values at that level from the response vector. The fitted values at level  $i$  are obtained by adding together the population fitted values (based only on the fixed effects estimates) and the estimated contributions of the random effects to the fitted values at grouping levels less or equal to  $i$ .

**Usage**

```
## S3 method for class 'lmeStruct'
residuals(object, level, conLin, lmeFit, ...)
```

**Arguments**

|                     |  |
|---------------------|--|
| <code>object</code> | an object inheriting from class " <a href="#">lmeStruct</a> ", representing a list of linear mixed-effects model components, such as <code>reStruct</code> , <code>corStruct</code> , and <code>varFunc</code> objects.  |
| <code>level</code>  | an optional integer vector giving the level(s) of grouping to be used in extracting the residuals from <code>object</code> . Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping.                            |
| <code>conLin</code> | an optional condensed linear model object, consisting of a list with components " <code>Xy</code> ", corresponding to a regression matrix ( $X$ ) combined with a response vector ( $y$ ), and " <code>logLik</code> ", corresponding to the log-likelihood of the underlying lme model. Defaults to <code>attr(object, "conLin")</code> . |
| <code>lmeFit</code> | an optional list with components <code>beta</code> and <code>b</code> containing respectively the fixed effects estimates and the random effects estimates to be used to calculate the residuals. Defaults to <code>attr(object, "lmeFit")</code> .  |
| <code>...</code>    | some methods for this generic accept optional arguments.   |

Value

if a single level of grouping is specified in `level`, the returned value is a vector with the residuals at the desired level; else, when multiple grouping levels are specified in `level`, the returned object is a matrix with columns given by the residuals at different levels.

Note

This method function is primarily used within the `lme` function.

|                               |                                 |
|-------------------------------|---------------------------------|
| <code>residuals.lmList</code> | <i>Extract lmList Residuals</i> |
|-------------------------------|---------------------------------|

---

Description

The residuals are extracted from each `lm` component of `object` and arranged into a list with as many components as `object`, or combined into a single vector.

Usage

```
## S3 method for class 'lmList'
residuals(object, type, subset, asList, ...)
```

Arguments

|                     |  |
|---------------------|--|
| <code>object</code> | an object inheriting from class " <code>lmList</code> ", representing a list of <code>lm</code> objects with a common model.   |
| <code>subset</code> | an optional character or integer vector naming the <code>lm</code> components of <code>object</code> from which the residuals are to be extracted. Default is <code>NULL</code> , in which case all components are used.   |
| <code>type</code>   | an optional character string specifying the type of residuals to be extracted. Options include <code>"response"</code> for the "raw" residuals (observed - fitted), <code>"pearson"</code> for the standardized residuals (raw residuals divided by the estimated residual standard error) using different standard errors for each <code>lm</code> fit, and <code>"pooled.pearson"</code> for the standardized residuals using a pooled estimate of the residual standard error. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to <code>"response"</code> . |
| <code>asList</code> | an optional logical value. If <code>TRUE</code> , the returned object is a list with the residuals split by groups; else the returned value is a vector. Defaults to <code>FALSE</code> .  |
| <code>...</code>    | some methods for this generic require additional arguments. None are used in this method.  |

**Value**

a list with components given by the residuals of each `lm` component of object, or a vector with the residuals for all `lm` components of object.

`residuals.nlmeStruct`    *Calculate nlmeStruct Residuals*

---

**Description**

The residuals at level  $i$  are obtained by subtracting the fitted values at that level from the response vector. The fitted values at level  $i$  are obtained by adding together the contributions from the estimated fixed effects and the estimated random effects at levels less or equal to  $i$  and evaluating the model function at the resulting estimated parameters.

**Usage**

```
## S3 method for class 'nlmeStruct'
residuals(object, level, conLin, ...)
```

**Arguments**

|                     |   |
|---------------------|---|
| <code>object</code> | an object inheriting from class " <a href="#">nlmeStruct</a> ", representing a list of mixed-effects model components, such as <code>reStruct</code> , <code>corStruct</code> , and <code>varFunc</code> objects.   |
| <code>level</code>  | an optional integer vector giving the level(s) of grouping to be used in extracting the residuals from object. Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping.   |
| <code>conLin</code> | an optional condensed linear model object, consisting of a list with components " <code>Xy</code> ", corresponding to a regression matrix ( $X$ ) combined with a response vector ( $y$ ), and " <code>logLik</code> ", corresponding to the log-likelihood of the underlying nlme model. Defaults to <code>attr(object, "conLin")</code> . |
| <code>...</code>    | optional arguments to the residuals generic. Not used.  |

**Value**

if a single level of grouping is specified in `level`, the returned value is a vector with the residuals at the desired level; else, when multiple grouping levels are specified in `level`, the returned object is a matrix with columns given by the residuals at different levels.

**Note**

This method function is primarily used within the nlme function.

reStruct

*Random Effects Structure*

---

**Description**

This function is a constructor for the reStruct class, representing a random effects structure and consisting of a list of pdMat objects, plus a settings attribute containing information for the optimization algorithm used to fit the associated mixed-effects model.

**Usage**

```
reStruct(object, pdClass, REML, data)
## S3 method for class 'reStruct'
print(x, sigma, reEstimates, verbose, ...)
```

**Arguments**

|         |   |
|---------|---|
| object  | any of the following: (i) a one-sided formula of the form $\sim x_1 + \dots + x_n \mid g_1 / \dots / g_m$ , with $x_1 + \dots + x_n$ specifying the model for the random effects and $g_1 / \dots / g_m$ the grouping structure ( $m$ may be equal to 1, in which case no $/$ is required). The random effects formula will be repeated for all levels of grouping, in the case of multiple levels of grouping; (ii) a list of one-sided formulas of the form $\sim x_1 + \dots + x_n \mid g$ , with possibly different random effects models for each grouping level. The order of nesting will be assumed the same as the order of the elements in the list; (iii) a one-sided formula of the form $\sim x_1 + \dots + x_n$ , or a pdMat object with a formula (i.e. a non-NULL value for <code>formula(object)</code> ), or a list of such formulas or pdMat objects. In this case, the grouping structure formula will be derived from the data used to fit the mixed-effects model, which should inherit from class <code>groupedData</code> ; (iv) a named list of formulas or pdMat objects as in (iii), with the grouping factors as names. The order of nesting will be assumed the same as the order of the elements in the list; (v) an reStruct object. |
| pdClass | an optional character string with the name of the pdMat class to be used for the formulas in object. Defaults to "pdSymm" which corresponds to a general positive-definite matrix.  |

|             |  |
|-------------|--|
| REML        | an optional logical value. If TRUE, the associated mixed-effects model will be fitted using restricted maximum likelihood; else, if FALSE, maximum likelihood will be used. Defaults to FALSE.   |
| data        | an optional data frame in which to evaluate the variables used in the random effects formulas in object. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying pdMat objects. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called. |
| x           | an object inheriting from class reStruct to be printed.  |
| sigma       | an optional numeric value used as a multiplier for the square-root factors of the pdMat components (usually the estimated within-group standard deviation from a mixed-effects model). Defaults to 1.  |
| reEstimates | an optional list with the random effects estimates for each level of grouping. Only used when verbose = TRUE.  |
| verbose     | an optional logical value determining if the random effects estimates should be printed. Defaults to FALSE.  |
| ...         | Optional arguments can be given to other methods for this generic. None are used in this method.   |

Value

an object inheriting from class reStruct, representing a random effects structure.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

rs1
```

---

|              |   |
|--------------|---|
| simulate.lme | <i>Simulate Results from lme Models</i> |
|--------------|---|

---

Description

The model object is fit to the data. Using the fitted values of the parameters, nsim new data vectors from this model are simulated. Both object and m2 are fit by maximum likelihood (ML) and/or by restricted maximum likelihood (REML) to each of the simulated data vectors.

Usage

```
## S3 method for class 'lme'
simulate(object, nsim = 1, seed = , m2,
         method = c("REML", "ML"), niterEM = c(40, 200), useGen, ...)
```

## Arguments

|         |  |
|---------|--|
| object  | an object inheriting from class " <a href="#">lme</a> ", representing a fitted linear mixed-effects model, or a list containing an lme model specification. If given as a list, it should contain components fixed, data, and random with values suitable for a call to <a href="#">lme</a> . This argument defines the null model.  |
| m2      | an " <a href="#">lme</a> " object or a list, like object containing a second lme model specification. This argument defines the alternative model. If given as a list, only those parts of the specification that change between model object and m2 need to be specified.   |
| seed    | an optional integer that is passed to <code>set.seed</code> . Defaults to a random integer.  |
| method  | an optional character array. If it includes "REML" the models are fit by maximizing the restricted log-likelihood. If it includes "ML" the log-likelihood is maximized. Defaults to <code>c("REML", "ML")</code> , in which case both methods are used.  |
| nsim    | an optional positive integer specifying the number of simulations to perform. Defaults to 1. <b>This has changed. Previously the default was 1000.</b>   |
| niterEM | an optional integer vector of length 2 giving the number of iterations of the EM algorithm to apply when fitting the object and m2 to each simulated set of data. Defaults to <code>c(40, 200)</code> .  |
| useGen  | an optional logical value. If TRUE, numerical derivatives are used to obtain the gradient and the Hessian of the log-likelihood in the optimization algorithm in the <code>ms</code> function. If FALSE, the default algorithm in <code>ms</code> for functions that do not incorporate gradient and Hessian attributes is used. Default depends on the " <a href="#">pdMat</a> " classes used in object and m2: if both are standard classes (see <a href="#">pdClasses</a> ) then defaults to TRUE, otherwise defaults to FALSE. |
| ...     | optional additional arguments. None are used.  |

## Value

an object of class `simulate.lme` with components `null` and `alt`. Each of these has components `ML` and/or `REML` which are matrices. An attribute called `Random.seed` contains the seed that was used for the random number generator.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

                   random = ~ 1 | Subject), nsim = 200,
               m2 = list(random = ~ age | Subject))
```

---

solve.pdMat

*Calculate Inverse of a Positive-Definite Matrix*

---

**Description**

The positive-definite matrix represented by a is inverted and assigned to a.

**Usage**

```
## S3 method for class 'pdMat'
solve(a, b, ...)
```

**Arguments**

|     |   |
|-----|---|
| a   | an object inheriting from class " <a href="#">pdMat</a> ", representing a positive definite matrix.               |
| b   | this argument is only included for consistency with the generic function and is not used in this method function. |
| ... | some methods for this generic require additional arguments. None are used in this method.                         |

**Value**

a pdMat object similar to a, but with coefficients corresponding to the inverse of the positive-definite matrix represented by a.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[pdMat](#)

**Examples**

```

solve(pd1)
```

---

solve.reStruct

*Apply Solve to an reStruct Object*

---

**Description**

Solve is applied to each pdMat component of a, which results in inverting the positive-definite matrices they represent.

**Usage**

```
## S3 method for class 'reStruct'
solve(a, b, ...)
```

Arguments

- a an object inheriting from class "reStruct", representing a random effects structure and consisting of a list of pdMat objects.
- b this argument is only included for consistency with the generic function and is not used in this method function.
- ... some methods for this generic require additional arguments. None are used in this method.

Value

an reStruct object similar to a, but with the pdMat components representing the inverses of the matrices represented by the components of a.

Description

The Soybean data frame has 412 rows and 5 columns.

Format

This data frame contains the following columns:

- Plot** a factor giving a unique identifier for each plot.
- Variety** a factor indicating the variety; Forrest (F) or Plant Introduction \#416937 (P).
- Year** a factor indicating the year the plot was planted.
- Time** a numeric vector giving the time the sample was taken (days after planting).
- weight** a numeric vector giving the average leaf weight per plant (g).

Details

These data are described in Davidian and Giltinan (1995, 1.1.3, p.7) as “Data from an experiment to compare growth patterns of two genotypes of soybeans: Plant Introduction \#416937 (P), an experimental strain, and Forrest (F), a commercial variety.”

Davidian, M. and Giltinan, D. M. (1995), *Nonlinear Models for Repeated Measurement Data*, Chapman and Hall, London.

**Examples**

```
summary(fm1 <- nlsList(SSlogis, data = Soybean))
```

---

splitFormula

*Split a Formula*

---

**Description**

Splits the right hand side of form into a list of subformulas according to the presence of sep. The left hand side of form, if present, will be ignored. The length of the returned list will be equal to the number of occurrences of sep in form plus one.

**Usage**

```
splitFormula(form, sep)
```

**Arguments**

|      |  |
|------|--|
| form | a formula object.  |
| sep  | an optional character string specifying the separator to be used for splitting the formula. Defaults to "/". |

**Value**

a list of formulas, corresponding to the split of form according to sep.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

|        |                               |
|--------|-------------------------------|
| Spruce | <i>Growth of Spruce Trees</i> |
|--------|-------------------------------|

---

### Description

The Spruce data frame has 1027 rows and 4 columns.

### Format

This data frame contains the following columns:

**Tree** a factor giving a unique identifier for each tree.

**days** a numeric vector giving the number of days since the beginning of the experiment.

**logSize** a numeric vector giving the logarithm of an estimate of the volume of the tree trunk.

**plot** a factor identifying the plot in which the tree was grown.

### Details

Diggle, Liang, and Zeger (1994, Example 1.3, page 5) describe data on the growth of spruce trees that have been exposed to an ozone-rich atmosphere or to a normal atmosphere.

### Source

|-------------------|-------------------------------------|
| summary.corStruct | <i>Summarize a corStruct Object</i> |
|-------------------|-------------------------------------|

---

### Description

This method function prepares object to be printed using the `print.summary` method, by changing its class and adding a `structName` attribute to it.

### Usage

```
## S3 method for class 'corStruct'
summary(object, structName, ...)
```

### Arguments

|                         |  |
|-------------------------|--|
| <code>object</code>     | an object inheriting from class " <code>corStruct</code> ", representing a correlation structure.  |
| <code>structName</code> | an optional character string defining the type of correlation structure associated with <code>object</code> , to be used in the <code>print.summary</code> method. Defaults to <code>class(object)[1]</code> . |
| <code>...</code>        | some methods for this generic require additional arguments. None are used in this method.  |

Value

an object identical to object, but with its class changed to summary.corStruct and an additional attribute structName. The returned value inherits from the same classes as object.

Author(s)

José Pinheiro and Douglas Bates

```

---

|             |   |
|-------------|---|
| summary.gls | <i>Summarize a Generalized Least Squares gls Object</i> |
|-------------|---|

---

Description

Additional information about the linear model fit represented by object is extracted and included as components of object.

Usage

```
## S3 method for class 'gls'
summary(object, verbose, ...)
```

Arguments

- object      an object inheriting from class "[gls](#)", representing a generalized least squares fitted linear model.
- verbose     an optional logical value used to control the amount of output when the object is printed. Defaults to FALSE.
- ...         some methods for this generic require additional arguments. None are used in this method.

Value

an object inheriting from class summary.gls with all components included in object (see [glsObject](#) for a full description of the components) plus the following components:

- corBeta     approximate correlation matrix for the coefficients estimates
- tTable      a matrix with columns Value, Std. Error, t-value, and p-value representing respectively the coefficients estimates, their approximate standard errors, the ratios between the estimates and their standard errors, and the associated p-value under a *t* approximation. Rows correspond to the different coefficients.

|           |   |
|-----------|---|
| residuals | if more than five observations are used in the gls fit, a vector with the minimum, first quartile, median, third quartile, and maximum of the residuals distribution; else the residuals. |
| AIC       | the Akaike Information Criterion corresponding to object.   |
| BIC       | the Bayesian Information Criterion corresponding to object.   |

Examples

```
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary,
           correlation = corAR1(form = ~ 1 | Mare))
summary(fm1)
coef(summary(fm1)) # "the matrix"
```

---

|             |                                |
|-------------|--------------------------------|
| summary.lme | <i>Summarize an lme Object</i> |
|-------------|--------------------------------|

---

Description

Additional information about the linear mixed-effects fit represented by object is extracted and included as components of object. The returned object has a [print](#) and a [coef](#) method, the latter returning the coefficient's tTtable.

Usage

```
## S3 method for class 'lme'
summary(object, adjustSigma, verbose, ...)
## S3 method for class 'summary.lme'
print(x, verbose = FALSE, ...)
```

Arguments

|             |  |
|-------------|--|
| object      | an object inheriting from class " <a href="#">lme</a> ", representing a fitted linear mixed-effects model.   |
| adjustSigma | an optional logical value. If TRUE and the estimation method used to obtain object was maximum likelihood, the residual standard error is multiplied by $\sqrt{n_{obs}/(n_{obs} - n_{par})}$ , converting it to a REML-like estimate. This argument is only used when a single fitted object is passed to the function. Default is TRUE. |
| verbose     | an optional logical value used to control the amount of output in the print.summary.lme method. Defaults to FALSE.   |
| ...         | additional optional arguments passed to methods, mainly for the <a href="#">print</a> method.  |
| x           | a "summary.lme" object. !  |

**Value**

an object inheriting from class `summary.lme` with all components included in `object` (see [lmeObject](#) for a full description of the components) plus the following components:

|                        |   |
|------------------------|---|
| <code>corFixed</code>  | approximate correlation matrix for the fixed effects estimates.   |
| <code>tTable</code>    | a matrix with columns named Value, Std. Error, DF, t-value, and p-value representing respectively the fixed effects estimates, their approximate standard errors, the denominator degrees of freedom, the ratios between the estimates and their standard errors, and the associated p-value from a t distribution. Rows correspond to the different fixed effects. |
| <code>residuals</code> | if more than five observations are used in the <code>lme</code> fit, a vector with the minimum, first quartile, median, third quartile, and maximum of the innermost grouping level residuals distribution; else the innermost grouping level residuals.  |
| <code>AIC</code>       | the Akaike Information Criterion corresponding to <code>object</code> .   |
| <code>BIC</code>       | the Bayesian Information Criterion corresponding to <code>object</code> .   |

```

---

|                             |  |
|-----------------------------|--|
| <code>summary.lmList</code> | <i>Summarize an <code>lmList</code> Object</i> |
|-----------------------------|--|

---

**Description**

The `summary.lm` method is applied to each `lm` component of `object` to produce summary information on the individual fits, which is organized into a list of summary statistics. The returned object is suitable for printing with the `print.summary.lmList` method.

**Usage**

```
## S3 method for class 'lmList'
summary(object, pool, ...)
```

**Arguments**

|                     |  |
|---------------------|--|
| <code>object</code> | an object inheriting from class " <a href="#">lmList</a> ", representing a list of <code>lm</code> fitted objects.   |
| <code>pool</code>   | an optional logical value indicating whether a pooled estimate of the residual standard error should be used. Default is <code>attr(object, "pool")</code> . |
| <code>...</code>    | some methods for this generic require additional arguments. None are used in this method.  |

**Value**

a list with summary statistics obtained by applying `summary.lm` to the elements of object, inheriting from class `summary.lmList`. The components of value are:

|                           |  |
|---------------------------|--|
| <code>call</code>         | a list containing an image of the <code>lmList</code> call that produced object.   |
| <code>coefficients</code> | a three dimensional array with summary information on the <code>lm</code> coefficients. The first dimension corresponds to the names of the object components, the second dimension is given by "Value", "Std. Error", "t value", and "Pr(> t )", corresponding, respectively, to the coefficient estimates and their associated standard errors, t-values, and p-values. The third dimension is given by the coefficients names.  |
| <code>correlation</code>  | a three dimensional array with the correlations between the individual <code>lm</code> coefficient estimates. The first dimension corresponds to the names of the object components. The third dimension is given by the coefficients names. For each coefficient, the rows of the associated array give the correlations between that coefficient and the remaining coefficients, by <code>lm</code> component.   |
| <code>cov.unscaled</code> | a three dimensional array with the unscaled variances/covariances for the individual <code>lm</code> coefficient estimates (giving the estimated variance/covariance for the coefficients, when multiplied by the estimated residual errors). The first dimension corresponds to the names of the object components. The third dimension is given by the coefficients names. For each coefficient, the rows of the associated array give the unscaled covariances between that coefficient and the remaining coefficients, by <code>lm</code> component. |
| <code>df</code>           | an array with the number of degrees of freedom for the model and for residuals, for each <code>lm</code> component.  |
| <code>df.residual</code>  | the total number of degrees of freedom for residuals, corresponding to the sum of residuals df of all <code>lm</code> components.  |
| <code>fstatistics</code>  | an array with the F test statistics and corresponding degrees of freedom, for each <code>lm</code> component.  |
| <code>pool</code>         | the value of the <code>pool</code> argument to the function.   |
| <code>r.squared</code>    | a vector with the multiple R-squared statistics for each <code>lm</code> component.  |
| <code>residuals</code>    | a list with components given by the residuals from individual <code>lm</code> fits.  |
| <code>RSE</code>          | the pooled estimate of the residual standard error.  |
| <code>sigma</code>        | a vector with the residual standard error estimates for the individual <code>lm</code> fits.   |
| <code>terms</code>        | the terms object used in fitting the individual <code>lm</code> components.  |

summary.modelStruct      *Summarize a modelStruct Object*

---

**Description**

This method function applies summary to each element of object.

**Usage**

```
## S3 method for class 'modelStruct'
summary(object, ...)
```

**Arguments**

|        |  |
|--------|--|
| object | an object inheriting from class "modelStruct", representing a list of model components, such as reStruct, corStruct and varFunc objects. |
| ...    | some methods for this generic require additional arguments. None are used in this method.  |

**Value**

a list with elements given by the summarized components of object. The returned value is of class summary.modelStruct, also inheriting from the same classes as object.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

```

---

summary.nlsList      *Summarize an nlsList Object*

---

**Description**

The summary function is applied to each nls component of object to produce summary information on the individual fits, which is organized into a list of summary statistics. The returned object is suitable for printing with the print.summary.nlsList method.

**Usage**

```
## S3 method for class 'nlsList'
summary(object, ...)
```

**Arguments**

|        |  |
|--------|--|
| object | an object inheriting from class " <code>nlsList</code> ", representing a list of nls fitted objects.   |
| ...    | optional arguments to the <code>summary.lmList</code> method. One such optional argument is <code>pool</code> , a logical value indicating whether a pooled estimate of the residual standard error should be used. Default is <code>attr(object, "pool")</code> . |

**Value**

a list with summary statistics obtained by applying `summary` to the elements of `object`, inheriting from class `summary.nlsList`. The components of `value` are:

|                           |   |
|---------------------------|---|
| <code>call</code>         | a list containing an image of the <code>nlsList</code> call that produced <code>object</code> .   |
| <code>parameters</code>   | a three dimensional array with summary information on the nls coefficients. The first dimension corresponds to the names of the object components, the second dimension is given by "Value", "Std. Error", "t value", and "Pr(> t )", corresponding, respectively, to the coefficient estimates and their associated standard errors, t-values, and p-values. The third dimension is given by the coefficients names.   |
| <code>correlation</code>  | a three dimensional array with the correlations between the individual nls coefficient estimates. The first dimension corresponds to the names of the object components. The third dimension is given by the coefficients names. For each coefficient, the rows of the associated array give the correlations between that coefficient and the remaining coefficients, by nls component.  |
| <code>cov.unscaled</code> | a three dimensional array with the unscaled variances/covariances for the individual lm coefficient estimates (giving the estimated variance/covariance for the coefficients, when multiplied by the estimated residual errors). The first dimension corresponds to the names of the object components. The third dimension is given by the coefficients names. For each coefficient, the rows of the associated array give the unscaled covariances between that coefficient and the remaining coefficients, by nls component. |
| <code>df</code>           | an array with the number of degrees of freedom for the model and for residuals, for each nls component.   |
| <code>df.residual</code>  | the total number of degrees of freedom for residuals, corresponding to the sum of residuals df of all nls components.   |
| <code>pool</code>         | the value of the <code>pool</code> argument to the function.  |
| <code>RSE</code>          | the pooled estimate of the residual standard error.   |
| <code>sigma</code>        | a vector with the residual standard error estimates for the individual lm fits.   |

summary.pdMat

*Summarize a pdMat Object***Description**

Attributes structName and noCorrelation, with the values of the corresponding arguments to the method function, are appended to object and its class is changed to summary.pdMat.

**Usage**

```
## S3 method for class 'pdMat'
summary(object, structName, noCorrelation, ...)
```

**Arguments**

|               |  |
|---------------|--|
| object        | an object inheriting from class " <a href="#">pdMat</a> ", representing a positive definite matrix.  |
| structName    | an optional character string with a description of the pdMat class. Default depends on the method function: "Blocked" for pdBlocked, "Compound Symmetry" for pdCompSymm, "Diagonal" for pdDiag, "Multiple of an Identity" for pdIdent, "General Positive-Definite, Natural Parametrization" for pdNatural, "General Positive-Definite" for pdSymm, and data.class(object) for pdMat. |
| noCorrelation | an optional logical value indicating whether correlations are to be printed in print.summary.pdMat. Default depends on the method function: FALSE for pdDiag and pdIdent, and TRUE for all other classes.  |
| ...           | some methods for this generic require additional arguments. None are used in this method.  |

**Value**

an object similar to object, with additional attributes structName and noCorrelation, inheriting from class summary.pdMat.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

|--------------------|------------------------------------|
| update.modelStruct | <i>Update a modelStruct Object</i> |
|--------------------|------------------------------------|

---

### Description

This method function updates each element of object, allowing the access to data.

### Usage

```
## S3 method for class 'modelStruct'
update(object, data, ...)
```

### Arguments

|        |  |
|--------|--|
| object | an object inheriting from class "modelStruct", representing a list of model components, such as corStruct and varFunc objects. |
| data   | a data frame in which to evaluate the variables needed for updating the elements of object.                                    |
| ...    | some methods for this generic require additional arguments. None are used in this method.                                      |

### Value

an object similar to object (same class, length, and names), but with updated elements.

### Note

This method function is primarily used within model fitting functions, such as lme and gls, that allow model components such as variance functions.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

|----------------|------------------------------|
| update.varFunc | <i>Update varFunc Object</i> |
|----------------|------------------------------|

---

### Description

If the formula(object) includes a "." term, representing a fitted object, the variance covariate needs to be updated upon completion of an optimization cycle (in which the variance function weights are kept fixed). This method function allows a reevaluation of the variance covariate using the current fitted object and, optionally, other variables in the original data.

Usage

```
## S3 method for class 'varFunc'  
update(object, data, ...)
```

Arguments

|        |   |
|--------|---|
| object | an object inheriting from class " <b>varFunc</b> ", representing a variance function structure.   |
| data   | a list with a component named "." with the current version of the fitted object (from which fitted values, coefficients, and residuals can be extracted) and, if necessary, other variables used to evaluate the variance covariate(s). |
| ...    | some methods for this generic require additional arguments. None are used in this method.   |

Value

if formula(object) includes a "." term, an varFunc object similar to object, but with the variance covariate reevaluated at the current fitted object value; else object is returned unchanged.

|------------|----------------------------------|
| varClasses | <i>Variance Function Classes</i> |
|------------|----------------------------------|

---

Description

Standard classes of variance function structures (varFunc) available in the nlme package. Covariates included in the variance function, denoted by variance covariates, may involve functions of the fitted model object, such as the fitted values and the residuals. Different coefficients may be assigned to the levels of a classification factor.

Value

Available standard classes:

|               |   |
|---------------|---|
| varExp        | exponential of a variance covariate.  |
| varPower      | power of a variance covariate.  |
| varConstPower | constant plus power of a variance covariate.  |
| varIdent      | constant variance(s), generally used to allow different variances according to the levels of a classification factor. |
| varFixed      | fixed weights, determined by a variance covariate.  |
| varComb       | combination of variance functions.  |

**Note**

Users may define their own varFunc classes by specifying a constructor function and, at a minimum, methods for the functions `coef`, `coef<-`, and `initialize`. For examples of these functions, see the methods for class `varPower`.

|         |  |
|---------|--|
| varComb | <i>Combination of Variance Functions</i> |
|---------|--|

---

**Description**

This function is a constructor for the `varComb` class, representing a combination of variance functions. The corresponding variance function is equal to the product of the variance functions of the `varFunc` objects listed in . . . .

**Usage**

```
varComb(. . .)
```

**Arguments**

. . .                      objects inheriting from class `varFunc` representing variance function structures.

**Value**

a `varComb` object representing a combination of variance functions, also inheriting from class `varFunc`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

```
vf1 <- varComb(varIdent(form = ~1|Sex), varPower())
```

varConstPower

*Constant Plus Power Variance Function***Description**

This function is a constructor for the varConstPower class, representing a constant plus power variance function structure. Letting  $v$  denote the variance covariate and  $\sigma^2(v)$  denote the variance function evaluated at  $v$ , the constant plus power variance function is defined as  $\sigma^2(v) = (\theta_1 + |v|_2^\theta)^2$ , where  $\theta_1, \theta_2$  are the variance function coefficients. When a grouping factor is present, different  $\theta_1, \theta_2$  are used for each factor level.

**Usage**

```
varConstPower(const, power, form, fixed)
```

**Arguments**

- |              |  |
|--------------|--|
| const, power | optional numeric vectors, or lists of numeric values, with, respectively, the coefficients for the constant and the power terms. Both arguments must have length one, unless a grouping factor is specified in form. If either argument has length greater than one, it must have names which identify its elements to the levels of the grouping factor defined in form. If a grouping factor is present in form and the argument has length one, its value will be assigned to all grouping levels. Only positive values are allowed for const. Default is <code>numeric(0)</code> , which results in a vector of zeros of appropriate length being assigned to the coefficients when object is initialized (corresponding to constant variance equal to one).   |
| form         | an optional one-sided formula of the form <code>~ v</code> , or <code>~ v   g</code> , specifying a variance covariate $v$ and, optionally, a grouping factor $g$ for the coefficients. The variance covariate must evaluate to a numeric vector and may involve expressions using <code>"."</code> , representing a fitted model object from which fitted values ( <code>fitted(.)</code> ) and residuals ( <code>resid(.)</code> ) can be extracted (this allows the variance covariate to be updated during the optimization of an object function). When a grouping factor is present in form, a different coefficient value is used for each of its levels. Several grouping variables may be simultaneously specified, separated by the <code>*</code> operator, as in <code>~ v   g1 * g2 * g3</code> . In this case, the levels of each grouping variable are pasted together and the resulting factor is used to group the observations. Defaults to <code>~ fitted(.)</code> representing a variance covariate given by the fitted values of a fitted model object and no grouping factor. |
| fixed        | an optional list with components <code>const</code> and/or <code>power</code> , consisting of numeric vectors, or lists of numeric values, specifying the values at which some or all of the coefficients in the variance function should be fixed. If a grouping factor is specified in form, the components of <code>fixed</code> must have names identifying which coefficients are to be fixed. Coefficients included in <code>fixed</code> are not allowed to vary during the optimization of an objective function. Defaults to <code>NULL</code> , corresponding to no fixed coefficients.  |

**Value**

a varConstPower object representing a constant plus power variance function structure, also inheriting from class varFunc.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

**Examples**

```
vf1 <- varConstPower(1.2, 0.2, form = ~age|Sex)
```

---

|         |  |
|---------|--|
| VarCorr | <i>Extract variance and correlation components</i> |
|---------|--|

---

**Description**

This function calculates the estimated variances, standard deviations, and correlations between the random-effects terms in a linear mixed-effects model, of class "[lme](#)", or a nonlinear mixed-effects model, of class "[nlme](#)". The within-group error variance and standard deviation are also calculated.

**Usage**

```
VarCorr(x, sigma = 1, ...)
## S3 method for class 'lme'
VarCorr(x, sigma = 1, rdig = 3, ...)
## and identical signature for classes 'pdMat' and 'pdBlocked'
```

**Arguments**

|                    |  |
|--------------------|--|
| <code>x</code>     | a fitted model object, usually an object inheriting from class " <a href="#">lme</a> ".                          |
| <code>sigma</code> | an optional numeric value used as a multiplier for the standard deviations. Default is 1.                        |
| <code>rdig</code>  | an optional integer value specifying the number of digits used to represent correlation estimates. Default is 3. |
| <code>...</code>   | further optional arguments passed to other methods (none for the methods documented here).                       |

**Value**

a matrix with the estimated variances, standard deviations, and correlations for the random effects. The first two columns, named `Variance` and `StdDev`, give, respectively, the variance and the standard deviations. If there are correlation components in the random effects model, the third column, named `Corr`, and the remaining unnamed columns give the estimated correlations among random effects within the same level of grouping. The within-group error variance and standard deviation are included as the last row in the matrix.

VarCorr(fm1)
```

---

varExp

*Exponential Variance Function*

---

**Description**

This function is a constructor for the `varExp` class, representing an exponential variance function structure. Letting  $v$  denote the variance covariate and  $\sigma^2(v)$  denote the variance function evaluated at  $v$ , the exponential variance function is defined as  $\sigma^2(v) = \exp(2\theta v)$ , where  $\theta$  is the variance function coefficient. When a grouping factor is present, a different  $\theta$  is used for each factor level.

**Usage**

```
varExp(value, form, fixed)
```

**Arguments**

- |       |   |
|-------|---|
| value | an optional numeric vector, or list of numeric values, with the variance function coefficients. Value must have length one, unless a grouping factor is specified in <code>form</code> . If <code>value</code> has length greater than one, it must have names which identify its elements to the levels of the grouping factor defined in <code>form</code> . If a grouping factor is present in <code>form</code> and <code>value</code> has length one, its value will be assigned to all grouping levels. Default is <code>numeric(0)</code> , which results in a vector of zeros of appropriate length being assigned to the coefficients when object is initialized (corresponding to constant variance equal to one).  |
| form  | an optional one-sided formula of the form <code>~ v</code> , or <code>~ v   g</code> , specifying a variance covariate <code>v</code> and, optionally, a grouping factor <code>g</code> for the coefficients. The variance covariate must evaluate to a numeric vector and may involve expressions using <code>"."</code> , representing a fitted model object from which fitted values ( <code>fitted(.)</code> ) and residuals ( <code>resid(.)</code> ) can be extracted (this allows the variance covariate to be updated during the optimization of an object function). When a grouping factor is present in <code>form</code> , a different coefficient value is used for each of its levels. Several grouping variables may be simultaneously specified, separated by the <code>*</code> operator, like in <code>~ v   g1 * g2 * g3</code> . In this case, the levels of each grouping variable are pasted together and the resulting factor is used to group |

the observations. Defaults to `~ fitted(.)` representing a variance covariate given by the fitted values of a fitted model object and no grouping factor.

`fixed` an optional numeric vector, or list of numeric values, specifying the values at which some or all of the coefficients in the variance function should be fixed. If a grouping factor is specified in `form`, `fixed` must have names identifying which coefficients are to be fixed. Coefficients included in `fixed` are not allowed to vary during the optimization of an objective function. Defaults to `NULL`, corresponding to no fixed coefficients.

**Value**

a `varExp` object representing an exponential variance function structure, also inheriting from class `varFunc`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

vf1 <- varExp(0.2, form = ~age|Sex)
```

---

|          |                                |
|----------|--------------------------------|
| varFixed | <i>Fixed Variance Function</i> |
|----------|--------------------------------|

---

**Description**

This function is a constructor for the `varFixed` class, representing a variance function with fixed variances. Letting  $v$  denote the variance covariate defined in `value`, the variance function  $\sigma^2(v)$  for this class is  $\sigma^2(v) = |v|$ . The variance covariate  $v$  is evaluated once at initialization and remains fixed thereafter. No coefficients are required to represent this variance function.

**Usage**

```
varFixed(value)
```

**Arguments**

`value` a one-sided formula of the form `~ v` specifying a variance covariate `v`. Grouping factors are ignored.

**Value**

a `varFixed` object representing a fixed variance function structure, also inheriting from class `varFunc`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

---

varFunc

*Variance Function Structure*

---

**Description**

If object is a one-sided formula, it is used as the argument to `varFixed` and the resulting object is returned. Else, if object inherits from class `varFunc`, it is returned unchanged.

**Usage**

```
varFunc(object)
```

**Arguments**

|        |  |
|--------|--|
| object | either an one-sided formula specifying a variance covariate, or an object inheriting from class <code>varFunc</code> , representing a variance function structure. |
|--------|--|

**Value**

an object from class `varFunc`, representing a variance function structure.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**Examples**

```
vf1 <- varFunc(~age)
```

varIdent

*Constant Variance Function***Description**

This function is a constructor for the `varIdent` class, representing a constant variance function structure. If no grouping factor is present in `form`, the variance function is constant and equal to one, and no coefficients required to represent it. When `form` includes a grouping factor with  $M > 1$  levels, the variance function allows  $M$  different variances, one for each level of the factor. For identifiability reasons, the coefficients of the variance function represent the ratios between the variances and a reference variance (corresponding to a reference group level). Therefore, only  $M - 1$  coefficients are needed to represent the variance function. By default, if the elements in `value` are unnamed, the first group level is taken as the reference level.

**Usage**

```
varIdent(value, form, fixed)
```

**Arguments**

- |       |  |
|-------|--|
| value | an optional numeric vector, or list of numeric values, with the variance function coefficients. If no grouping factor is present in <code>form</code> , this argument is ignored, as the resulting variance function contains no coefficients. If <code>value</code> has length one, its value is repeated for all coefficients in the variance function. If <code>value</code> has length greater than one, it must have length equal to the number of grouping levels minus one and names which identify its elements to the levels of the grouping factor. Only positive values are allowed for this argument. Default is <code>numeric(0)</code> , which results in a vector of zeros of appropriate length being assigned to the coefficients when object is initialized (corresponding to constant variance equal to one). |
| form  | an optional one-sided formula of the form <code>~ v</code> , or <code>~ v   g</code> , specifying a variance covariate <code>v</code> and, optionally, a grouping factor <code>g</code> for the coefficients. The variance covariate is ignored in this variance function. When a grouping factor is present in <code>form</code> , a different coefficient value is used for each of its levels less one reference level (see description section below). Several grouping variables may be simultaneously specified, separated by the <code>*</code> operator, like in <code>~ v   g1 * g2 * g3</code> . In this case, the levels of each grouping variable are pasted together and the resulting factor is used to group the observations. Defaults to <code>~ 1</code> .   |
| fixed | an optional numeric vector, or list of numeric values, specifying the values at which some or all of the coefficients in the variance function should be fixed. It must have names identifying which coefficients are to be fixed. Coefficients included in <code>fixed</code> are not allowed to vary during the optimization of an objective function. Defaults to <code>NULL</code> , corresponding to no fixed coefficients.   |

**Value**

a `varIdent` object representing a constant variance function structure, also inheriting from class `varFunc`.

vf1 <- varIdent(c(Female = 0.5), form = ~ 1 | Sex)
```

---

|           |                                 |
|-----------|---------------------------------|
| Variogram | <i>Calculate Semi-variogram</i> |
|-----------|---------------------------------|

---

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `default`, `gls` and `lme`. See the appropriate method documentation for a description of the arguments.

**Usage**

```
Variogram(object, distance, ...)
```

**Arguments**

|                       |  |
|-----------------------|--|
| <code>object</code>   | a numeric vector with the values to be used for calculating the semi-variogram, usually a residual vector from a fitted model.   |
| <code>distance</code> | a numeric vector with the pairwise distances corresponding to the elements of <code>object</code> . The order of the elements in <code>distance</code> must correspond to the pairs (1,2), (1,3), ..., (n-1,n), with <code>n</code> representing the length of <code>object</code> , and must have length $n(n-1)/2$ . |
| <code>...</code>      | some methods for this generic function require additional arguments.   |

**Value**

will depend on the method function used; see the appropriate documentation.

|-------------------|---------------------------------|
| Variogram.default | <i>Calculate Semi-variogram</i> |
|-------------------|---------------------------------|

---

**Description**

This method function calculates the semi-variogram for an arbitrary vector object, according to the distances in distance. For each pair of elements  $x, y$  in object, the corresponding semi-variogram is  $(x - y)^2/2$ . The semi-variogram is useful for identifying and modeling spatial correlation structures in observations with constant expectation and constant variance.

**Usage**

```
## Default S3 method:
Variogram(object, distance, ...)
```

**Arguments**

|          |  |
|----------|--|
| object   | a numeric vector with the values to be used for calculating the semi-variogram, usually a residual vector from a fitted model.   |
| distance | a numeric vector with the pairwise distances corresponding to the elements of object. The order of the elements in distance must correspond to the pairs (1,2), (1,3), ..., (n-1,n), with n representing the length of object, and must have length $n(n-1)/2$ . |
| ...      | some methods for this generic require additional arguments. None are used in this method.  |

**Value**

a data frame with columns variog and dist representing, respectively, the semi-variogram values and the corresponding distances. The returned value inherits from class Variogram.

fm1 <- lm(follicles ~ sin(2 * pi * Time) + cos(2 * pi * Time), Ovary,
          subset = Mare == 1)
Variogram(resid(fm1), dist(1:29))[1:10,]

## End(Not run)
```

Variogram.gls

*Calculate Semi-variogram for Residuals from a gls Object***Description**

This method function calculates the semi-variogram for the residuals from a gls fit. The semi-variogram values are calculated for pairs of residuals within the same group level, if a grouping factor is present. If collapse is different from "none", the individual semi-variogram values are collapsed using either a robust estimator (robust = TRUE) defined in Cressie (1993), or the average of the values within the same distance interval. The semi-variogram is useful for modeling the error term correlation structure.

**Usage**

```
## S3 method for class 'gls'
Variogram(object, distance, form, resType, data,
          na.action, maxDist, length.out, collapse, nint, breaks,
          robust, metric, ...)
```

**Arguments**

|          |  |
|----------|--|
| object   | an object inheriting from class " <a href="#">gls</a> ", representing a generalized least squares fitted model.  |
| distance | an optional numeric vector with the distances between residual pairs. If a grouping variable is present, only the distances between residual pairs within the same group should be given. If missing, the distances are calculated based on the values of the arguments form, data, and metric, unless object includes a corSpatial element, in which case the associated covariate (obtained with the getCovariate method) is used.   |
| form     | an optional one-sided formula specifying the covariate(s) to be used for calculating the distances between residual pairs and, optionally, a grouping factor for partitioning the residuals (which must appear to the right of a   operator in form). Default is ~1, implying that the observation order within the groups is used to obtain the distances.  |
| resType  | an optional character string specifying the type of residuals to be used. If "response", the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson". |

|                         |   |
|-------------------------|---|
| <code>data</code>       | an optional data frame in which to interpret the variables in form. By default, the same data used to fit object is used.   |
| <code>na.action</code>  | a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes an error message to be printed and the function to terminate, if there are any incomplete observations.  |
| <code>maxDist</code>    | an optional numeric value for the maximum distance used for calculating the semi-variogram between two residuals. By default all residual pairs are included.   |
| <code>length.out</code> | an optional integer value. When object includes a <code>corSpatial</code> element, its semi-variogram values are calculated and this argument is used as the <code>length.out</code> argument to the corresponding <code>Variogram</code> method. Defaults to 50.   |
| <code>collapse</code>   | an optional character string specifying the type of collapsing to be applied to the individual semi-variogram values. If equal to "quantiles", the semi-variogram values are split according to quantiles of the distance distribution, with equal number of observations per group, with possibly varying distance interval lengths. Else, if "fixed", the semi-variogram values are divided according to distance intervals of equal lengths, with possibly different number of observations per interval. Else, if "none", no collapsing is used and the individual semi-variogram values are returned. Defaults to "quantiles". |
| <code>nint</code>       | an optional integer with the number of intervals to be used when collapsing the semi-variogram values. Defaults to 20.  |
| <code>robust</code>     | an optional logical value specifying if a robust semi-variogram estimator should be used when collapsing the individual values. If TRUE the robust estimator is used. Defaults to FALSE.  |
| <code>breaks</code>     | an optional numeric vector with the breakpoints for the distance intervals to be used in collapsing the semi-variogram values. If not missing, the option specified in <code>collapse</code> is ignored.  |
| <code>metric</code>     | an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".  |
| <code>...</code>        | some methods for this generic require additional arguments. None are used in this method.   |

### Value

a data frame with columns `variog` and `dist` representing, respectively, the semi-variogram values and the corresponding distances. If the semi-variogram values are collapsed, an extra column, `n.pairs`, with the number of residual pairs used in each semi-variogram calculation, is included in the returned data frame. If object includes a `corSpatial` element, a data frame with its corresponding semi-variogram is included in the returned value, as an attribute `"modelVariog"`. The returned value inherits from class `Variogram`.

|---------------|--|
| Variogram.lme | <i>Calculate Semi-variogram for Residuals from an lme Object</i> |
|---------------|--|

---

Description

This method function calculates the semi-variogram for the within-group residuals from an lme fit. The semi-variogram values are calculated for pairs of residuals within the same group. If collapse is different from "none", the individual semi-variogram values are collapsed using either a robust estimator (robust = TRUE) defined in Cressie (1993), or the average of the values within the same distance interval. The semi-variogram is useful for modeling the error term correlation structure.

Usage

```
## S3 method for class 'lme'
Variogram(object, distance, form, resType, data,
          na.action, maxDist, length.out, collapse, nint, breaks,
          robust, metric, ...)
```

Arguments

- |          |  |
|----------|--|
| object   | an object inheriting from class " <a href="#">lme</a> ", representing a fitted linear mixed-effects model.   |
| distance | an optional numeric vector with the distances between residual pairs. If a grouping variable is present, only the distances between residual pairs within the same group should be given. If missing, the distances are calculated based on the values of the arguments form, data, and metric, unless object includes a corSpatial element, in which case the associated covariate (obtained with the getCovariate method) is used. |
| form     | an optional one-sided formula specifying the covariate(s) to be used for calculating the distances between residual pairs and, optionally, a grouping factor for partitioning the residuals (which must appear to the right of a   operator in form). Default is ~1, implying that the observation order within the groups is used to obtain the distances.  |

|                         |   |
|-------------------------|---|
| <code>resType</code>    | an optional character string specifying the type of residuals to be used. If "response", the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson".  |
| <code>data</code>       | an optional data frame in which to interpret the variables in form. By default, the same data used to fit object is used.   |
| <code>na.action</code>  | a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes an error message to be printed and the function to terminate, if there are any incomplete observations.  |
| <code>maxDist</code>    | an optional numeric value for the maximum distance used for calculating the semi-variogram between two residuals. By default all residual pairs are included.   |
| <code>length.out</code> | an optional integer value. When object includes a <code>corSpatial</code> element, its semi-variogram values are calculated and this argument is used as the <code>length.out</code> argument to the corresponding <code>Variogram</code> method. Defaults to 50.   |
| <code>collapse</code>   | an optional character string specifying the type of collapsing to be applied to the individual semi-variogram values. If equal to "quantiles", the semi-variogram values are split according to quantiles of the distance distribution, with equal number of observations per group, with possibly varying distance interval lengths. Else, if "fixed", the semi-variogram values are divided according to distance intervals of equal lengths, with possibly different number of observations per interval. Else, if "none", no collapsing is used and the individual semi-variogram values are returned. Defaults to "quantiles". |
| <code>nint</code>       | an optional integer with the number of intervals to be used when collapsing the semi-variogram values. Defaults to 20.  |
| <code>robust</code>     | an optional logical value specifying if a robust semi-variogram estimator should be used when collapsing the individual values. If TRUE the robust estimator is used. Defaults to FALSE.  |
| <code>breaks</code>     | an optional numeric vector with the breakpoints for the distance intervals to be used in collapsing the semi-variogram values. If not missing, the option specified in <code>collapse</code> is ignored.  |
| <code>metric</code>     | an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".  |
| <code>...</code>        | some methods for this generic require additional arguments. None are used in this method.   |

### Value

a data frame with columns `variog` and `dist` representing, respectively, the semi-variogram values and the corresponding distances. If the semi-variogram values are collapsed, an extra column, `n.pairs`, with the number of residual pairs used in each semi-variogram calculation, is included in the returned data frame. If object includes a `corSpatial` element, a data frame with its corresponding semi-variogram is included in the returned value, as an attribute `"modelVariog"`. The returned value inherits from class `Variogram`.

```

---

varPower

*Power Variance Function*

---

**Description**

This function is a constructor for the `varPower` class, representing a power variance function structure. Letting  $v$  denote the variance covariate and  $\sigma^2(v)$  denote the variance function evaluated at  $v$ , the power variance function is defined as  $\sigma^2(v) = |v|^{2\theta}$ , where  $\theta$  is the variance function coefficient. When a grouping factor is present, a different  $\theta$  is used for each factor level.

**Usage**

```
varPower(value, form, fixed)
```

**Arguments**

|       |  |
|-------|--|
| value | an optional numeric vector, or list of numeric values, with the variance function coefficients. Value must have length one, unless a grouping factor is specified in <code>form</code> . If <code>value</code> has length greater than one, it must have names which identify its elements to the levels of the grouping factor defined in <code>form</code> . If a grouping factor is present in <code>form</code> and <code>value</code> has length one, its value will be assigned to all grouping levels. Default is <code>numeric(0)</code> , which results in a vector of zeros of appropriate length being assigned to the coefficients when object is initialized (corresponding to constant variance equal to one).   |
| form  | an optional one-sided formula of the form <code>~ v</code> , or <code>~ v   g</code> , specifying a variance covariate <code>v</code> and, optionally, a grouping factor <code>g</code> for the coefficients. The variance covariate must evaluate to a numeric vector and may involve expressions using <code>"."</code> , representing a fitted model object from which fitted values ( <code>fitted(.)</code> ) and residuals ( <code>resid(.)</code> ) can be extracted (this allows the variance covariate to be updated during the optimization of an object function). When a grouping factor is present in <code>form</code> , a different coefficient value is used for each of its levels. Several grouping variables may be simultaneously specified, separated by the <code>*</code> operator, like in <code>~ v   g1 * g2 * g3</code> . In this case, the levels of each grouping variable are pasted together and the resulting factor is used to group the observations. Defaults to <code>~ fitted(.)</code> representing a variance covariate given by the fitted values of a fitted model object and no grouping factor. |

**fixed** an optional numeric vector, or list of numeric values, specifying the values at which some or all of the coefficients in the variance function should be fixed. If a grouping factor is specified in `form`, `fixed` must have names identifying which coefficients are to be fixed. Coefficients included in `fixed` are not allowed to vary during the optimization of an objective function. Defaults to `NULL`, corresponding to no fixed coefficients.

### Value

a `varPower` object representing a power variance function structure, also inheriting from class `varFunc`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### References

varWeights

*Extract Variance Function Weights*

---

### Description

The inverse of the standard deviations corresponding to the variance function structure represented by object are returned.

### Usage

```
varWeights(object)
```

### Arguments

**object** an object inheriting from class `varFunc`, representing a variance function structure.

### Value

if object has a `weights` attribute, its value is returned; else `NULL` is returned.

### Author(s)

[,pdMat

*Subscript a pdMat Object***Description**

This method function extracts sub-matrices from the positive-definite matrix represented by `x`.

**Usage**

```
## S3 method for class 'pdMat'
x[i, j, drop = TRUE]
## S3 replacement method for class 'pdMat'
x[i, j] <- value
```

**Arguments**

|                    |   |
|--------------------|---|
| <code>x</code>     | an object inheriting from class " <code>pdMat</code> " representing a positive-definite matrix.   |
| <code>i, j</code>  | optional subscripts applying respectively to the rows and columns of the positive-definite matrix represented by object. When <code>i</code> ( <code>j</code> ) is omitted, all rows (columns) are extracted. |
| <code>drop</code>  | a logical value. If <code>TRUE</code> , single rows or columns are converted to vectors. If <code>FALSE</code> the returned value retains its matrix representation.  |
| <code>value</code> | a vector, or matrix, with the replacement values for the relevant piece of the matrix represented by <code>x</code> .   |

**Value**

if `i` and `j` are identical, the returned value will be `pdMat` object with the same class as `x`. Otherwise, the returned value will be a matrix. In the case a single row (or column) is selected, the returned value may be converted to a vector, according to the rules above.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

[\[,pdMat](#)

**Examples**

```
pd1 <- pdSymm(diag(3))
pd1[1, , drop = FALSE]
pd1[1:2, 1:2] <- 3 * diag(2)
```

## Chapter 26

# The nnet package

---

class.ind

*Generates Class Indicator Matrix from a Factor*

---

### Description

Generates a class indicator function from a given factor.

### Usage

```
class.ind(cl)
```

### Arguments

cl                      factor or vector of classes for cases.

### Value

a matrix which is zero except for the column corresponding to the class.

### References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

### Examples

```
# The function is currently defined as
class.ind <- function(cl)
{
  n <- length(cl)
  cl <- as.factor(cl)
  x <- matrix(0, n, length(levels(cl)) )
  x[(1:n) + n*(unclass(cl)-1)] <- 1
  dimnames(x) <- list(names(cl), levels(cl))
  x
}
```

---

multinom

*Fit Multinomial Log-linear Models*

---

## Description

Fits multinomial log-linear models via neural networks.

## Usage

```
multinom(formula, data, weights, subset, na.action,
         contrasts = NULL, Hess = FALSE, summ = 0, censored = FALSE,
         model = FALSE, ...)
```

## Arguments

|           |  |
|-----------|--|
| formula   | a formula expression as for regression models, of the form response ~ predictors. The response should be a factor or a matrix with K columns, which will be interpreted as counts for each of K classes. A log-linear model is fitted, with coefficients zero for the first class. An offset can be included: it should be a numeric matrix with K columns if the response is either a matrix with K columns or a factor with K >= 2 classes, or a numeric vector for a response factor with 2 levels. See the documentation of <a href="#">formula()</a> for other details. |
| data      | an optional data frame in which to interpret the variables occurring in formula.   |
| weights   | optional case weights in fitting.  |
| subset    | expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.  |
| na.action | a function to filter missing data.   |
| contrasts | a list of contrasts to be used for some or all of the factors appearing as variables in the model formula.   |
| Hess      | logical for whether the Hessian (the observed/expected information matrix) should be returned.   |
| summ      | integer; if non-zero summarize by deleting duplicate rows and adjust weights. Methods 1 and 2 differ in speed (2 uses C); method 3 also combines rows with the same X and different Y, which changes the baseline for the deviance.  |
| censored  | If Y is a matrix with K columns, interpret the entries as one for possible classes, zero for impossible classes, rather than as counts.  |
| model     | logical. If true, the model frame is saved as component model of the returned object.  |
| ...       | additional arguments for nnet  |

## Details

multinom calls [nnet](#). The variables on the rhs of the formula should be roughly scaled to [0,1] or the fit will be slow or may not converge at all.

**Value**

A `nnet` object with additional components:

|          |  |
|----------|--|
| deviance | the residual deviance, compared to the full saturated model (that explains individual observations exactly). Also, minus twice log-likelihood. |
| edf      | the (effective) number of degrees of freedom used by the model   |
| AIC      | the AIC for this fit.  |
| Hessian  | (if <code>Hess</code> is true).  |
| model    | (if <code>model</code> is true).   |

**References**

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

**See Also**

[nnet](#)

**Examples**

```
options(contrasts = c("contr.treatment", "contr.poly"))
library(MASS)
example(birthwt)
(bwt.mu <- multinom(low ~ ., bwt))
```

---

nnet

---

*Fit Neural Networks*

---

**Description**

Fit single-hidden-layer neural network, possibly with skip-layer connections.

**Usage**

```
nnet(x, ...)
```

```
## S3 method for class 'formula'
nnet(formula, data, weights, ...,
      subset, na.action, contrasts = NULL)
```

```
## Default S3 method:
nnet(x, y, weights, size, Wts, mask,
      linout = FALSE, entropy = FALSE, softmax = FALSE,
      censored = FALSE, skip = FALSE, rang = 0.7, decay = 0,
      maxit = 100, Hess = FALSE, trace = TRUE, MaxNWts = 1000,
      abstol = 1.0e-4, reltol = 1.0e-8, ...)
```

**Arguments**

|                        |   |
|------------------------|---|
| <code>formula</code>   | A formula of the form <code>class ~ x1 + x2 + ...</code> .  |
| <code>x</code>         | matrix or data frame of <code>x</code> values for examples.   |
| <code>y</code>         | matrix or data frame of target values for examples.   |
| <code>weights</code>   | (case) weights for each example – if missing defaults to 1.   |
| <code>size</code>      | number of units in the hidden layer. Can be zero if there are skip-layer units.   |
| <code>data</code>      | Data frame from which variables specified in <code>formula</code> are preferentially to be taken.   |
| <code>subset</code>    | An index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)  |
| <code>na.action</code> | A function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. An alternative is <code>na.omit</code> , which leads to rejection of cases with missing values on any required variable. (NOTE: If given, this argument must be named.) |
| <code>contrasts</code> | a list of contrasts to be used for some or all of the factors appearing as variables in the model formula.  |
| <code>Wts</code>       | initial parameter vector. If missing chosen at random.  |
| <code>mask</code>      | logical vector indicating which parameters should be optimized (default all).   |
| <code>linout</code>    | switch for linear output units. Default logistic output units.  |
| <code>entropy</code>   | switch for entropy (= maximum conditional likelihood) fitting. Default by least-squares.  |
| <code>softmax</code>   | switch for softmax (log-linear model) and maximum conditional likelihood fitting. <code>linout</code> , <code>entropy</code> , <code>softmax</code> and <code>censored</code> are mutually exclusive.   |
| <code>censored</code>  | A variant on <code>softmax</code> , in which non-zero targets mean possible classes. Thus for <code>softmax</code> a row of (0, 1, 1) means one example each of classes 2 and 3, but for <code>censored</code> it means one example whose class is only known to be 2 or 3.             |
| <code>skip</code>      | switch to add skip-layer connections from input to output.  |
| <code>rang</code>      | Initial random weights on <code>[-rang, rang]</code> . Value about 0.5 unless the inputs are large, in which case it should be chosen so that <code>rang * max( x )</code> is about 1.  |
| <code>decay</code>     | parameter for weight decay. Default 0.  |
| <code>maxit</code>     | maximum number of iterations. Default 100.  |
| <code>Hess</code>      | If true, the Hessian of the measure of fit at the best set of weights found is returned as component <code>Hessian</code> .   |
| <code>trace</code>     | switch for tracing optimization. Default TRUE.  |
| <code>MaxNWts</code>   | The maximum allowable number of weights. There is no intrinsic limit in the code, but increasing <code>MaxNWts</code> will probably allow fits that are very slow and time-consuming.   |
| <code>abstol</code>    | Stop if the fit criterion falls below <code>abstol</code> , indicating an essentially perfect fit.  |
| <code>reltol</code>    | Stop if the optimizer is unable to reduce the fit criterion by a factor of at least <code>1 - reltol</code> .   |
| <code>...</code>       | arguments passed to or from other methods.  |

## Details

If the response in formula is a factor, an appropriate classification network is constructed; this has one output and entropy fit if the number of levels is two, and a number of outputs equal to the number of classes and a softmax output stage for more levels. If the response is not a factor, it is passed on unchanged to `nnet.default`.

Optimization is done via the BFGS method of [optim](#).

## Value

object of class "nnet" or "nnet.formula". Mostly internal structure, but has components

|                            |   |
|----------------------------|---|
| <code>wts</code>           | the best set of weights found                                   |
| <code>value</code>         | value of fitting criterion plus weight decay term.              |
| <code>fitted.values</code> | the fitted values for the training data.                        |
| <code>residuals</code>     | the residuals for the training data.                            |
| <code>convergence</code>   | 1 if the maximum number of iterations was reached, otherwise 0. |

## Examples

```
# use half the iris data
ir <- rbind(iris3[,1],iris3[,2],iris3[,3])
targets <- class.ind( c(rep("s", 50), rep("c", 50), rep("v", 50)) )
samp <- c(sample(1:50,25), sample(51:100,25), sample(101:150,25))
ir1 <- nnet(ir[samp,], targets[samp,], size = 2, rang = 0.1,
            decay = 5e-4, maxit = 200)
test.cl <- function(true, pred) {
  true <- max.col(true)
  cres <- max.col(pred)
  table(true, cres)
}
test.cl(targets[-samp,], predict(ir1, ir[-samp,]))

# or
ird <- data.frame(rbind(iris3[,1], iris3[,2], iris3[,3]),
                  species = factor(c(rep("s",50), rep("c", 50), rep("v", 50))))
ir.nn2 <- nnet(species ~ ., data = ird, subset = samp, size = 2, rang = 0.1,
               decay = 5e-4, maxit = 200)
table(ird$species[-samp], predict(ir.nn2, ird[-samp,], type = "class"))
```

nnetHess

*Evaluates Hessian for a Neural Network***Description**

Evaluates the Hessian (matrix of second derivatives) of the specified neural network. Normally called via argument Hess=TRUE to `nnet` or via `vcov.multinom`.

**Usage**

```
nnetHess(net, x, y, weights)
```

**Arguments**

|                      |  |
|----------------------|--|
| <code>net</code>     | object of class <code>nnet</code> as returned by <code>nnet</code> . |
| <code>x</code>       | training data.   |
| <code>y</code>       | classes for training data.   |
| <code>weights</code> | the (case) weights used in the <code>nnet</code> fit.                |

**Value**

square symmetric matrix of the Hessian evaluated at the weights stored in the net.

**References**

Ripley, B. D. (1996) *Pattern Recognition and Neural Networks*. Cambridge.  
 Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

**Examples**

```
# use half the iris data
ir <- rbind(iris3[,1], iris3[,2], iris3[,3])
targets <- matrix(c(rep(c(1,0,0),50), rep(c(0,1,0),50), rep(c(0,0,1),50)),
  150, 3, byrow=TRUE)
samp <- c(sample(1:50,25), sample(51:100,25), sample(101:150,25))
ir1 <- nnet(ir[samp,], targets[samp,], size=2, rang=0.1, decay=5e-4, maxit=200)
eigen(nnetHess(ir1, ir[samp,], targets[samp,]), TRUE)$values
```

predict.nnet

*Predict New Examples by a Trained Neural Net***Description**

Predict new examples by a trained neural net.

**Usage**

```
## S3 method for class 'nnet'
predict(object, newdata, type = c("raw", "class"), ...)
```

**Arguments**

|         |  |
|---------|--|
| object  | an object of class nnet as returned by nnet.   |
| newdata | matrix or data frame of test examples. A vector is considered to be a row vector comprising a single case. |
| type    | Type of output   |
| ...     | arguments passed to or from other methods.   |

**Details**

This function is a method for the generic function `predict()` for class "nnet". It can be invoked by calling `predict(x)` for an object `x` of the appropriate class, or directly by calling `predict.nnet(x)` regardless of the class of the object.

**Value**

If `type = "raw"`, the matrix of values returned by the trained network; if `type = "class"`, the corresponding class (which is probably only useful if the net was generated by `nnet.formula`).

**References**

Ripley, B. D. (1996) *Pattern Recognition and Neural Networks*. Cambridge.

---

which.is.max

*Find Maximum Position in Vector*

---

## Description

Find the maximum position in a vector, breaking ties at random.

## Usage

```
which.is.max(x)
```

## Arguments

x                      a vector

## Details

Ties are broken at random.

## Value

index of a maximal value.

## References

## Chapter 27

# The rpart package

---

`car.test.frame`

*Automobile Data from 'Consumer Reports' 1990*

---

### Description

The `car.test.frame` data frame has 60 rows and 8 columns, giving data on makes of cars taken from the April, 1990 issue of *Consumer Reports*. This is part of a larger dataset, some columns of which are given in [cu.summary](#).

### Usage

`car.test.frame`

### Format

This data frame contains the following columns:

Price a numeric vector giving the list price in US dollars of a standard model

Country of origin, a factor with levels 'France', 'Germany', 'Japan', 'Japan/USA', 'Korea', 'Mexico', 'Sweden' and 'USA'

Reliability a numeric vector coded 1 to 5.

Mileage fuel consumption miles per US gallon, as tested.

Type a factor with levels Compact Large Medium Small Sporty Van

Weight kerb weight in pounds.

Disp. the engine capacity (displacement) in litres.

HP the net horsepower of the vehicle.

### Source

*Consumer Reports*, April, 1990, pp. 235–288 quoted in

John M. Chambers and Trevor J. Hastie eds. (1992) *Statistical Models in S*, Wadsworth and Brooks/Cole, Pacific Grove, CA, pp. 46–47.

**See Also**

[car90](#), [cu.summary](#)

**Examples**

```
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
summary(z.auto)
```

---

car90

---

*Automobile Data from 'Consumer Reports' 1990*

---

**Description**

Data on 111 cars, taken from pages 235–255, 281–285 and 287–288 of the April 1990 *Consumer Reports* Magazine.

**Usage**

```
data(car90)
```

**Format**

The data frame contains the following columns

**Country** a factor giving the country in which the car was manufactured

**Disp** engine displacement in cubic inches

**Disp2** engine displacement in liters

**Eng.Rev** engine revolutions per mile, or engine speed at 60 mph

**Front.Hd** distance between the car's head-liner and the head of a 5 ft. 9 in. front seat passenger, in inches, as measured by CU

**Frt.Leg.Room** maximum front leg room, in inches, as measured by CU

**Frt.Shld** front shoulder room, in inches, as measured by CU

**Gear.Ratio** the overall gear ratio, high gear, for manual transmission

**Gear2** the overall gear ratio, high gear, for automatic transmission

**HP** net horsepower

**HP.revs** the red line—the maximum safe engine speed in rpm

**Height** height of car, in inches, as supplied by manufacturer

**Length** overall length, in inches, as supplied by manufacturer

**Luggage** luggage space

**Mileage** a numeric vector of gas mileage in miles/gallon as tested by CU; contains NAs.

**Model2** alternate name, if the car was sold under two labels

**Price** list price with standard equipment, in dollars

**Rear.Hd** distance between the car's head-liner and the head of a 5 ft 9 in. rear seat passenger, in inches, as measured by CU

**Rear.Seating** rear fore-and-aft seating room, in inches, as measured by CU

**RearShld** rear shoulder room, in inches, as measured by CU

**Reliability** an ordered factor with levels ‘Much worse’ < ‘worse’ < ‘average’ < ‘better’ < ‘Much better’: contains NAs.

**Rim** factor giving the rim size

**Sratio.m** Number of turns of the steering wheel required for a turn of 30 foot radius, manual steering

**Sratio.p** Number of turns of the steering wheel required for a turn of 30 foot radius, power steering

**Steering** steering type offered: manual, power, or both

**Tank** fuel refill capacity in gallons

**Tires** factor giving tire size

**Trans1** manual transmission, a factor with levels ‘’, ‘man.4’, ‘man.5’ and ‘man.6’

**Trans2** automatic transmission, a factor with levels ‘’, ‘auto.3’, ‘auto.4’, and ‘auto.CVT’. No car is missing both the manual and automatic transmission variables, but several had both as options

**Turning** the radius of the turning circle in feet

**Type** a factor giving the general type of car. The levels are: ‘Small’, ‘Sporty’, ‘Compact’, ‘Medium’, ‘Large’, ‘Van’

**Weight** an order statistic giving the relative weights of the cars; 1 is the lightest and 111 is the heaviest

**Wheel.base** length of wheelbase, in inches, as supplied by manufacturer

**Width** width of car, in inches, as supplied by manufacturer

## Source

This is derived (with permission) from the data set `car.all` in S-PLUS, but with some further clean up of variable names and definitions.

## See Also

[car.test.frame](#), [cu.summary](#) for extracts from other versions of the dataset.

## Examples

```
data(car90)
plot(car90$Price/1000, car90$Weight,
     xlab = "Price (thousands)", ylab = "Weight (lbs)")
mlowess <- function(x, y, ...) {
  keep <- !(is.na(x) | is.na(y))
  lowess(x[keep], y[keep], ...)
}
with(car90, lines(mlowess(Price/1000, Weight, f = 0.5)))
```

---

`cu.summary`*Automobile Data from 'Consumer Reports' 1990*

---

## Description

The `cu.summary` data frame has 117 rows and 5 columns, giving data on makes of cars taken from the April, 1990 issue of *Consumer Reports*.

## Usage

```
cu.summary
```

## Format

This data frame contains the following columns:

Price a numeric vector giving the list price in US dollars of a standard model

Country of origin, a factor with levels 'Brazil', 'England', 'France', 'Germany', 'Japan', 'Japan/USA', 'Korea', 'Mexico', 'Sweden' and 'USA'

Reliability an ordered factor with levels 'Much worse' < 'worse' < 'average' < 'better' < 'Much better'

Mileage fuel consumption miles per US gallon, as tested.

Type a factor with levels Compact Large Medium Small Sporty Van

---

 kyphosis

*Data on Children who have had Corrective Spinal Surgery*

---

**Description**

The kyphosis data frame has 81 rows and 4 columns. representing data on children who have had corrective spinal surgery

**Usage**

```
kyphosis
```

**Format**

This data frame contains the following columns:

**Kyphosis** a factor with levels absent present indicating if a kyphosis (a type of deformation) was present after the operation.

**Age** in months

**Number** the number of vertebrae involved

**Start** the number of the first (topmost) vertebra operated on.

**Source**

John M. Chambers and Trevor J. Hastie eds. (1992) *Statistical Models in S*, Wadsworth and Brooks/Cole, Pacific Grove, CA.

**Examples**

```
fit <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis)
fit2 <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis,
             parms = list(prior = c(0.65, 0.35), split = "information"))
fit3 <- rpart(Kyphosis ~ Age + Number + Start, data=kyphosis,
             control = rpart.control(cp = 0.05))
par(mfrow = c(1,2), xpd = TRUE)
plot(fit)
text(fit, use.n = TRUE)
plot(fit2)
text(fit2, use.n = TRUE)
```

---

 labels.rpart

*Create Split Labels For an Rpart Object*

---

**Description**

This function provides labels for the branches of an rpart tree.

**Usage**

```
## S3 method for class 'rpart'
labels(object, digits = 4, minlength = 1L, pretty, collapse = TRUE, ...)
```

Arguments

|           |  |
|-----------|--|
| object    | fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function.   |
| digits    | the number of digits to be used for numeric values. All of the rpart functions that call labels explicitly set this value, with options("digits") as the default.  |
| minlength | the minimum length for abbreviation of character or factor variables. If 0 no abbreviation is done; if 1 single English letters are used, first lower case than upper case (with a maximum of 52 levels). If the value is greater than , the <a href="#">abbreviate</a> function is used, passed the minlength argument.   |
| pretty    | an argument included for compatibility with the <b>tree</b> package: pretty = 0 implies minlength = 0L, pretty = NULL implies minlength = 1L, and pretty = TRUE implies minlength = 4L.  |
| collapse  | logical. The returned set of labels is always of the same length as the number of nodes in the tree.<br><br>If collapse = TRUE (default), the returned value is a vector of labels for the branch leading into each node, with "root" as the label for the top node.<br><br>If FALSE, the returned value is a two column matrix of labels for the left and right branches leading out from each node, with "leaf" as the branch labels for terminal nodes. |
| ...       | optional arguments to abbreviate.  |

Value

Vector of split labels (collapse = TRUE) or matrix of left and right splits (collapse = FALSE) for the supplied rpart object. This function is called by printing methods for rpart and is not intended to be called directly by the users.

See Also

[abbreviate](#)

---

|               |   |
|---------------|---|
| meanvar.rpart | <i>Mean-Variance Plot for an Rpart Object</i> |
|---------------|---|

---

Description

Creates a plot on the current graphics device of the deviance of the node divided by the number of observations at the node. Also returns the node number.

Usage

```
meanvar(tree, ...)  
  
## S3 method for class 'rpart'  
meanvar(tree, xlab = "ave(y)", ylab = "ave(deviance)", ...)
```

Arguments

|      |  |
|------|--|
| tree | fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function. |
| xlab | x-axis label for the plot.   |
| ylab | y-axis label for the plot.   |
| ...  | additional graphical parameters may be supplied as arguments to this function.   |

Value

|   |   |
|---|---|
| an invisible list containing the following vectors is returned. |   |
| x   | fitted value at terminal nodes (yval).                      |
| y   | deviance of node divided by number of observations at node. |
| label   | node number.  |

Side Effects

a plot is put on the current graphics device.

See Also

[plot.rpart](#).

Examples

```
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
meanvar(z.auto, log = 'xy')
```

---

|          |  |
|----------|--|
| na.rpart | <i>Handles Missing Values in an Rpart Object</i> |
|----------|--|

---

Description

Handles missing values in an "rpart" object.

Usage

```
na.rpart(x)
```

Arguments

|   |                |
|---|----------------|
| x | a model frame. |
|---|----------------|

Details

Default function that handles missing values when calling the function rpart.  
It omits cases where part of the response is missing or all the explanatory variables are missing.

---

|            |  |
|------------|--|
| path.rpart | <i>Follow Paths to Selected Nodes of an Rpart Object</i> |
|------------|--|

---

**Description**

Returns a names list where each element contains the splits on the path from the root to the selected nodes.

**Usage**

```
path.rpart(tree, nodes, pretty = 0, print.it = TRUE)
```

**Arguments**

|          |   |
|----------|---|
| tree     | fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function.  |
| nodes    | an integer vector containing indices (node numbers) of all nodes for which paths are desired. If missing, user selects nodes as described below.  |
| pretty   | an integer denoting the extent to which factor levels in split labels will be abbreviated. A value of (0) signifies no abbreviation. A NULL, the default, signifies using elements of letters to represent the different factor levels. |
| print.it | Logical. Denotes whether paths will be printed out as nodes are interactively selected. Irrelevant if nodes argument is supplied.   |

**Details**

The function has a required argument as an rpart object and a list of nodes as optional arguments. Omitting a list of nodes will cause the function to wait for the user to select nodes from the dendrogram. It will return a list, with one component for each node specified or selected. The component contains the sequence of splits leading to that node. In the graphical interaction, the individual paths are printed out as nodes are selected.

**Value**

A named (by node) list, each element of which contains all the splits on the path from the root to the specified or selected nodes.

**Graphical Interaction**

A dendrogram of the rpart object is expected to be visible on the graphics device, and a graphics input device (e.g. a mouse) is required. Clicking (the selection button) on a node selects that node. This process may be repeated any number of times. Clicking the exit button will stop the selection process and return the list of paths.

**References**

This function was modified from path.tree in S.

**See Also**

[rpart](#)

**Examples**

```
fit <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis)
print(fit)
path.rpart(fit, node = c(11, 22))
```

plot.rpart

*Plot an Rpart Object***Description**

Plots an rpart object on the current graphics device.

**Usage**

```
## S3 method for class 'rpart'
plot(x, uniform = FALSE, branch = 1, compress = FALSE, nspace,
     margin = 0, minbranch = 0.3, ...)
```

**Arguments**

|           |   |
|-----------|---|
| x         | a fitted object of class "rpart", containing a classification, regression, or rate tree.  |
| uniform   | if TRUE, uniform vertical spacing of the nodes is used; this may be less cluttered when fitting a large plot onto a page. The default is to use a non-uniform spacing proportional to the error in the fit.   |
| branch    | controls the shape of the branches from parent to child node. Any number from 0 to 1 is allowed. A value of 1 gives square shouldered branches, a value of 0 give V shaped branches, with other values being intermediate.  |
| compress  | if FALSE, the leaf nodes will be at the horizontal plot coordinates of 1:nleaves. If TRUE, the routine attempts a more compact arrangement of the tree. The compaction algorithm assumes uniform=TRUE; surprisingly, the result is usually an improvement even when that is not the case.   |
| nspace    | the amount of extra space between a node with children and a leaf, as compared to the minimal space between leaves. Applies to compressed trees only. The default is the value of branch.   |
| margin    | an extra fraction of white space to leave around the borders of the tree. (Long labels sometimes get cut off by the default computation).   |
| minbranch | set the minimum length for a branch to minbranch times the average branch length. This parameter is ignored if uniform=TRUE. Sometimes a split will give very little improvement, or even (in the classification case) no improvement at all. A tree with branch lengths strictly proportional to improvement leaves no room to squeeze in node labels. |
| ...       | arguments to be passed to or from other methods.  |

**Details**

This function is a method for the generic function plot, for objects of class rpart. The y-coordinate of the top node of the tree will always be 1.

**Value**

The coordinates of the nodes are returned as a list, with components `x` and `y`.

**Side Effects**

An unlabeled plot is produced on the current graphics device: one being opened if needed.

In order to build up a plot in the usual S style, e.g., a separate `text` command for adding labels, some extra information about the plot needs be retained. This is kept in an environment in the package.

**See Also**

[rpart](#), [text.rpart](#)

**Examples**

```
fit <- rpart(Price ~ Mileage + Type + Country, cu.summary)
par(xpd = TRUE)
plot(fit, compress = TRUE)
text(fit, use.n = TRUE)
```

---

plotcp

*Plot a Complexity Parameter Table for an Rpart Fit*

---

**Description**

Gives a visual representation of the cross-validation results in an `rpart` object.

**Usage**

```
plotcp(x, minline = TRUE, lty = 3, col = 1,
       upper = c("size", "splits", "none"), ...)
```

**Arguments**

|                      |  |
|----------------------|--|
| <code>x</code>       | an object of class <code>"rpart"</code>  |
| <code>minline</code> | whether a horizontal line is drawn 1SE above the minimum of the curve.   |
| <code>lty</code>     | line type for this line  |
| <code>col</code>     | colour for this line   |
| <code>upper</code>   | what is plotted on the top axis: the size of the tree (the number of leaves), the number of splits or nothing. |
| <code>...</code>     | additional plotting parameters   |

**Details**

The set of possible cost-complexity prunings of a tree from a nested set. For the geometric means of the intervals of values of `cp` for which a pruning is optimal, a cross-validation has (usually) been done in the initial construction by [rpart](#). The `cptable` in the fit contains the mean and standard deviation of the errors in the cross-validated prediction against each of the geometric means, and these are plotted by this function. A good choice of `cp` for pruning is often the leftmost value for which the mean lies below the horizontal line.

**Value**

None.

**Side Effects**

A plot is produced on the current graphical device.

---

 post.rpart

---

*PostScript Presentation Plot of an Rpart Object*

---

**Description**

Generates a PostScript presentation plot of an rpart object.

**Usage**

```
post(tree, ...)

## S3 method for class 'rpart'
post(tree, title.,
      filename = paste(deparse(substitute(tree)), ".ps", sep = ""),
      digits = getOption("digits") - 2, pretty = TRUE,
      use.n = TRUE, horizontal = TRUE, ...)
```

**Arguments**

|            |   |
|------------|---|
| tree       | fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function.  |
| title.     | a title which appears at the top of the plot. By default, the name of the rpart endpoint is printed out.  |
| filename   | ASCII file to contain the output. By default, the name of the file is the name of the object given by rpart (with the suffix .ps added). If filename = "", the plot appears on the current graphical device.  |
| digits     | number of significant digits to include in numerical data.  |
| pretty     | an integer denoting the extent to which factor levels will be abbreviated in the character strings defining the splits; (0) signifies no abbreviation of levels. A NULL signifies using elements of letters to represent the different factor levels. The default (TRUE) indicates the maximum possible abbreviation. |
| use.n      | Logical. If TRUE (default), adds to label (\#events level1/\#events level2/etc. for method class, n for method anova, and \#events/n for methods poisson and exp).  |
| horizontal | Logical. If TRUE (default), plot is horizontal. If FALSE, plot appears as landscape.  |
| ...        | other arguments to the postscript function.   |

Details

The plot created uses the functions `plot.rpart` and `text.rpart` (with the fancy option). The settings were chosen because they looked good to us, but other options may be better, depending on the `rpart` object. Users are encouraged to write their own function containing favorite options.

Side Effects

a plot of `rpart` is created using the postscript driver, or the current device if `filename = ""`.

Examples

```
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
post(z.auto, file = "") # display tree on active device
# now construct postscript version on file "pretty.ps"
# with no title
post(z.auto, file = "pretty.ps", title = " ")
z.hp <- rpart(Mileage ~ Weight + HP, car.test.frame)
post(z.hp)
```

---

|               |   |
|---------------|---|
| predict.rpart | <i>Predictions from a Fitted Rpart Object</i> |
|---------------|---|

---

Description

Returns a vector of predicted responses from a fitted `rpart` object.

Usage

```
## S3 method for class 'rpart'
predict(object, newdata,
        type = c("vector", "prob", "class", "matrix"),
        na.action = na.pass, ...)
```

Arguments

|           |   |
|-----------|---|
| object    | fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the <code>rpart</code> function.   |
| newdata   | data frame containing the values at which predictions are required. The predictors referred to in the right side of <code>formula(object)</code> must be present by name in <code>newdata</code> . If missing, the fitted values are returned.  |
| type      | character string denoting the type of predicted value returned. If the <code>rpart</code> object is a classification tree, then the default is to return prob predictions, a matrix whose columns are the probability of the first, second, etc. class. (This agrees with the default behavior of <a href="#">tree</a> ). Otherwise, a vector result is returned. |
| na.action | a function to determine what should be done with missing values in <code>newdata</code> . The default is to pass them down the tree using surrogates in the way selected when the model was built. Other possibilities are <a href="#">na.omit</a> and <a href="#">na.fail</a> .  |
| ...       | further arguments passed to or from other methods.  |

## Details

This function is a method for the generic function `predict` for class `"rpart"`. It can be invoked by calling `predict` for an object of the appropriate class, or directly by calling `predict.rpart` regardless of the class of the object.

## Value

A new object is obtained by dropping `newdata` down the object. For factor predictors, if an observation contains a level not used to grow the tree, it is left at the deepest possible node and `frame$yval` at the node is the prediction.

If `type = "vector"`:

vector of predicted responses. For regression trees this is the mean response at the node, for Poisson trees it is the estimated response rate, and for classification trees it is the predicted class (as a number).

If `type = "prob"`:

(for a classification tree) a matrix of class probabilities.

If `type = "matrix"`:

a matrix of the full responses (`frame$yval2` if this exists, otherwise `frame$yval`). For regression trees, this is the mean response, for Poisson trees it is the response rate and the number of events at that node in the fitted tree, and for classification trees it is the concatenation of at least the predicted class, the class counts at that node in the fitted tree, and the class probabilities (some versions of **rpart** may contain further columns).

If `type = "class"`:

(for a classification tree) a factor of classifications based on the responses.

## See Also

## Examples

```
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
predict(z.auto)

fit <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis)
predict(fit, type = "prob") # class probabilities (default)
predict(fit, type = "vector") # level numbers
predict(fit, type = "class") # factor
predict(fit, type = "matrix") # level number, class frequencies, probabilities

sub <- c(sample(1:50, 25), sample(51:100, 25), sample(101:150, 25))
fit <- rpart(Species ~ ., data = iris, subset = sub)
fit
table(predict(fit, iris[-sub,], type = "class"), iris[-sub, "Species"])
```

---

print.rpart

*Print an Rpart Object*

---

## Description

This function prints an `rpart` object. It is a method for the generic function `print` of class `"rpart"`.

## Usage

```
## S3 method for class 'rpart'
print(x, minlength = 0, spaces = 2, cp, digits = getOption("digits"), ...)
```

## Arguments

|           |  |
|-----------|--|
| x         | fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function. |
| minlength | Controls the abbreviation of labels: see <a href="#">labels.rpart</a> .  |
| spaces    | the number of spaces to indent nodes of increasing depth.  |
| digits    | the number of digits of numbers to print.  |
| cp        | prune all nodes with a complexity less than cp from the printout. Ignored if unspecified.  |
| ...       | arguments to be passed to or from other methods.   |

## Details

This function is a method for the generic function print for class "rpart". It can be invoked by calling print for an object of the appropriate class, or directly by calling print.rpart regardless of the class of the object.

## Side Effects

A semi-graphical layout of the contents of x\$frame is printed. Indentation is used to convey the tree topology. Information for each node includes the node number, split, size, deviance, and fitted value. For the "class" method, the class probabilities are also printed.

  3) Weight<2567.5 15 186.93330 30.93333 *
```

## End(Not run)

---

printcp

---

*Displays CP table for Fitted Rpart Object*

---

## Description

Displays the cp table for fitted rpart object.

## Usage

```
printcp(x, digits = getOption("digits") - 2)
```

## Arguments

|        |  |
|--------|--|
| x      | fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function. |
| digits | the number of digits of numbers to print.  |

## Details

Prints a table of optimal prunings based on a complexity parameter.

---

prune.rpart

*Cost-complexity Pruning of an Rpart Object*

---

**Description**

Determines a nested sequence of subtrees of the supplied rpart object by recursively snipping off the least important splits, based on the complexity parameter (cp).

**Usage**

```
prune(tree, ...)

## S3 method for class 'rpart'
prune(tree, cp, ...)
```

**Arguments**

|      |  |
|------|--|
| tree | fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function. |
| cp   | Complexity parameter to which the rpart object will be trimmed.  |
| ...  | further arguments passed to or from other methods.   |

**Value**

A new rpart object that is trimmed to the value cp.

**See Also**

[rpart](#)

**Examples**

```
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
zp <- prune(z.auto, cp = 0.1)
plot(zp) #plot smaller rpart object
```

---

residuals.rpart

*Residuals From a Fitted Rpart Object*

---

**Description**

Method for residuals for an rpart object.

**Usage**

```
## S3 method for class 'rpart'
residuals(object, type = c("usual", "pearson", "deviance"), ...)
```

**Arguments**

|        |  |
|--------|--|
| object | fitted model object of class "rpart".  |
| type   | Indicates the type of residual desired.<br>For regression or anova trees all three residual definitions reduce to $y - \text{fitted}$ . This is the residual returned for user method trees as well.<br>For classification trees the usual residuals are the misclassification losses $L(\text{actual}, \text{predicted})$ where $L$ is the loss matrix. With default losses this residual is 0/1 for correct/incorrect classification. The pearson residual is $(1 - \text{fitted})/\sqrt{\text{fitted}(1 - \text{fitted})}$ and the deviance residual is $\sqrt{\text{minus twice log-arithm of fitted}}$ .<br>For poisson and exp (or survival) trees, the usual residual is the observed - expected number of events. The pearson and deviance residuals are as defined in McCullagh and Nelder. |
| ...    | further arguments passed to or from other methods.   |

**Value**

Vector of residuals of type type from a fitted rpart object.

**References**

McCullagh P. and Nelder, J. A. (1989) *Generalized Linear Models*. London: Chapman and Hall.

**Examples**

```
fit <- rpart(skips ~ Opening + Solder + Mask + PadType + Panel,
            data = solder, method = "anova")
summary(residuals(fit))
plot(predict(fit), residuals(fit))
```

rpart

*Recursive Partitioning and Regression Trees***Description**

Fit a rpart model

**Usage**

```
rpart(formula, data, weights, subset, na.action = na.rpart, method,
      model = FALSE, x = FALSE, y = TRUE, parms, control, cost, ...)
```

**Arguments**

|         |  |
|---------|--|
| formula | a <a href="#">formula</a> , with a response but no interaction terms. If this a a data frame, that is taken as the model frame (see <a href="#">model.frame</a> ). |
| data    | an optional data frame in which to interpret the variables named in the formula.   |
| weights | optional case weights.   |
| subset  | optional expression saying that only a subset of the rows of the data should be used in the fit.   |

|           |  |
|-----------|--|
| na.action | the default action deletes all observations for which y is missing, but keeps those in which one or more predictors are missing.   |
| method    | one of "anova", "poisson", "class" or "exp". If method is missing then the routine tries to make an intelligent guess. If y is a survival object, then method = "exp" is assumed, if y has 2 columns then method = "poisson" is assumed, if y is a factor then method = "class" is assumed, otherwise method = "anova" is assumed. It is wisest to specify the method directly, especially as more criteria may added to the function in future.<br><br>Alternatively, method can be a list of functions named init, split and eval. Examples are given in the file 'tests/usersplits.R' in the sources, and in the vignettes 'User Written Split Functions'.  |
| model     | if logical: keep a copy of the model frame in the result? If the input value for model is a model frame (likely from an earlier call to the rpart function), then this frame is used rather than constructing new data.  |
| x         | keep a copy of the x matrix in the result.   |
| y         | keep a copy of the dependent variable in the result. If missing and model is supplied this defaults to FALSE.  |
| parms     | optional parameters for the splitting function.<br>Anova splitting has no parameters.<br>Poisson splitting has a single parameter, the coefficient of variation of the prior distribution on the rates. The default value is 1.<br>Exponential splitting has the same parameter as Poisson.<br>For classification splitting, the list can contain any of: the vector of prior probabilities (component prior), the loss matrix (component loss) or the splitting index (component split). The priors must be positive and sum to 1. The loss matrix must have zeros on the diagonal and positive off-diagonal elements. The splitting index can be gini or information. The default priors are proportional to the data counts, the losses default to 1, and the split defaults to gini. |
| control   | a list of options that control details of the rpart algorithm. See <a href="#">rpart.control</a> .   |
| cost      | a vector of non-negative costs, one for each variable in the model. Defaults to one for all variables. These are scalings to be applied when considering splits, so the improvement on splitting on a variable is divided by its cost in deciding which split to choose.   |
| ...       | arguments to <a href="#">rpart.control</a> may also be specified in the call to rpart. They are checked against the list of valid arguments.   |

## Details

This differs from the `tree` function in S mainly in its handling of surrogate variables. In most details it follows Breiman *et. al* (1984) quite closely. R package **tree** provides a re-implementation of `tree`.

## Value

An object of class `rpart`. See [rpart.object](#).

## References

Breiman L., Friedman J. H., Olshen R. A., and Stone, C. J. (1984) *Classification and Regression Trees*. Wadsworth.

**See Also**

[rpart.control](#), [rpart.object](#), [summary.rpart](#), [print.rpart](#)

**Examples**

```
fit <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis)
fit2 <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis,
             parms = list(prior = c(.65,.35), split = "information"))
fit3 <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis,
             control = rpart.control(cp = 0.05))
par(mfrow = c(1,2), xpd = NA) # otherwise on some devices the text is clipped
plot(fit)
text(fit, use.n = TRUE)
plot(fit2)
text(fit2, use.n = TRUE)
```

---

rpart.control

*Control for Rpart Fits*

---

**Description**

Various parameters that control aspects of the rpart fit.

**Usage**

```
rpart.control(minsplit = 20, minbucket = round(minsplit/3), cp = 0.01,
             maxcompete = 4, maxsurrogate = 5, usesurrogate = 2, xval = 10,
             surrogatestyle = 0, maxdepth = 30, ...)
```

**Arguments**

|              |   |
|--------------|---|
| minsplit     | the minimum number of observations that must exist in a node in order for a split to be attempted.  |
| minbucket    | the minimum number of observations in any terminal <leaf> node. If only one of minbucket or minsplit is specified, the code either sets minsplit to minbucket*3 or minbucket to minsplit/3, as appropriate.   |
| cp           | complexity parameter. Any split that does not decrease the overall lack of fit by a factor of cp is not attempted. For instance, with anova splitting, this means that the overall R-squared must increase by cp at each step. The main role of this parameter is to save computing time by pruning off splits that are obviously not worthwhile. Essentially, the user informs the program that any split which does not improve the fit by cp will likely be pruned off by cross-validation, and that hence the program need not pursue it. |
| maxcompete   | the number of competitor splits retained in the output. It is useful to know not just which split was chosen, but which variable came in second, third, etc.  |
| maxsurrogate | the number of surrogate splits retained in the output. If this is set to zero the compute time will be reduced, since approximately half of the computational time (other than setup) is used in the search for surrogate splits.   |

|                |   |
|----------------|---|
| usesurrogate   | how to use surrogates in the splitting process. 0 means display only; an observation with a missing value for the primary split rule is not sent further down the tree. 1 means use surrogates, in order, to split subjects missing the primary variable; if all surrogates are missing the observation is not split. For value 2 ,if all surrogates are missing, then send the observation in the majority direction. A value of 0 corresponds to the action of tree, and 2 to the recommendations of Breiman <i>et.al</i> (1984). |
| xval           | number of cross-validations.  |
| surrogatestyle | controls the selection of a best surrogate. If set to 0 (default) the program uses the total number of correct classification for a potential surrogate variable, if set to 1 it uses the percent correct, calculated over the non-missing values of the surrogate. The first option more severely penalizes covariates with a large number of missing values.  |
| maxdepth       | Set the maximum depth of any node of the final tree, with the root node counted as depth 0. Values greater than 30 rpart will give nonsense results on 32-bit machines.   |
| ...            | mop up other arguments.   |

**Value**

A list containing the options.

**See Also**

[rpart](#)

---

|           |  |
|-----------|--|
| rpart.exp | <i>Initialization function for exponential fitting</i> |
|-----------|--|

---

**Description**

This function does the initialization step for rpart, when the response is a survival object. It rescales the data so as to have an exponential baseline hazard and then uses Poisson methods. This function would rarely if ever be called directly by a user.

**Usage**

rpart.exp(y, offset, parms, wt)

**Arguments**

|        |   |
|--------|---|
| y      | the response, which will be of class Surv   |
| offset | optional offset   |
| parms  | parameters controlling the fit. This is a list with components shrink and method. The first is the prior for the coefficient of variation of the predictions. The second is either "deviance" or "sqrt" and is the measure used for cross-validation. If values are missing the defaults are used, which are "deviance" for the method, and a shrinkage of 1.0 for the deviance method and 0 for the square root. |
| wt     | case weights, if present  |

**Value**

a list with the necessary initialization components

**Author(s)**

Terry Therneau

**See Also**

[rpart](#)

---

rpart.object

Recursive Partitioning and Regression Trees Object

---

**Description**

These are objects representing fitted rpart trees.

**Value**

|        |  |
|--------|--|
| frame  | data frame with one row for each node in the tree. The row.names of frame contain the (unique) node numbers that follow a binary ordering indexed by node depth. Columns of frame include var, a factor giving the names of the variables used in the split at each node (leaf nodes are denoted by the level "<leaf>"), n, the number of observations reaching the node, wt, the sum of case weights for observations reaching the node, dev, the deviance of the node, yval, the fitted value of the response at the node, and splits, a two column matrix of left and right split labels for each node. Also included in the frame are complexity, the complexity parameter at which this split will collapse, ncompete, the number of competitor splits recorded, and nsurrogate, the number of surrogate splits recorded.<br><br>Extra response information which may be present is in yval2, which contains the number of events at the node (poisson tree), or a matrix containing the fitted class, the class counts for each node, the class probabilities and the 'node probability' (classification trees). |
| where  | an integer vector of the same length as the number of observations in the root node, containing the row number of frame corresponding to the leaf node that each observation falls into.   |
| call   | an image of the call that produced the object, but with the arguments all named and with the actual formula included as the formula argument. To re-evaluate the call, say update(tree).   |
| terms  | an object of class c("terms", "formula") (see <a href="#">terms.object</a> ) summarizing the formula. Used by various methods, but typically not of direct relevance to users.   |
| splits | a numeric matrix describing the splits: only present if there are any. The row label is the name of the split variable, and columns are count, the number of observations (which are not missing and are of positive weight) sent left or right by the split (for competitor splits this is the number that would have been sent left or right had this split been used, for surrogate splits it is the number missing the primary split variable which were decided using this surrogate), ncat,  |

|                     |   |
|---------------------|---|
|                     | the number of categories or levels for the variable (+/-1 for a continuous variable), improve, which is the improvement in deviance given by this split, or, for surrogates, the concordance of the surrogate with the primary, and index, the numeric split point. The last column adj gives the adjusted concordance for surrogate splits. For a factor, the index column contains the row number of the csplit matrix. For a continuous variable, the sign of ncat determines whether the subset $x < \text{cutpoint}$ or $x > \text{cutpoint}$ is sent to the left. |
| csplit              | an integer matrix. (Only present only if at least one of the split variables is a factor or ordered factor.) There is a row for each such split, and the number of columns is the largest number of levels in the factors. Which row is given by the index column of the splits matrix. The columns record 1 if that level of the factor goes to the left, 3 if it goes to the right, and 2 if that level is not present at this node of the tree (or not defined for the factor).  |
| method              | character string: the method used to grow the tree. One of "class", "exp", "poisson", "anova" or "user" (if splitting functions were supplied).   |
| cptable             | a matrix of information on the optimal prunings based on a complexity parameter.  |
| variable.importance | a named numeric vector giving the importance of each variable. (Only present if there are any splits.) When printed by <code>summary.rpart</code> these are rescaled to add to 100.   |
| numresp             | integer number of responses; the number of levels for a factor response.  |
| parms, control      | a record of the arguments supplied, which defaults filled in.   |
| functions           | the summary, print and text functions for method used.  |
| ordered             | a named logical vector recording for each variable if it was an ordered factor.   |
| na.action           | (where relevant) information returned by <code>model.frame</code> on the special handling of NAs derived from the na.action argument.   |

There may be `attributes` "xlevels" and "levels" recording the levels of any factor splitting variables and of a factor response respectively.

Optional components include the model frame (`model`), the matrix of predictors (`x`) and the response variable (`y`) used to construct the `rpart` object.

Structure

The following components must be included in a legitimate `rpart` object.

See Also

[rpart](#).

---

|           |  |
|-----------|--|
| rsq.rpart | <i>Plots the Approximate R-Square for the Different Splits</i> |
|-----------|--|

---

Description

Produces 2 plots. The first plots the r-square (apparent and apparent - from cross-validation) versus the number of splits. The second plots the Relative Error(cross-validation) +/- 1-SE from cross-validation versus the number of splits.

Usage

rsq.rpart(x)

Arguments

x                      fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function.

Side Effects

Two plots are produced.

Note

The labels are only appropriate for the "anova" method.

Examples

```
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
rsq.rpart(z.auto)
```

---

|            |   |
|------------|---|
| snip.rpart | <i>Snip Subtrees of an Rpart Object</i> |
|------------|---|

---

Description

Creates a "snipped" rpart object, containing the nodes that remain after selected subtrees have been snipped off. The user can snip nodes using the toss argument, or interactively by clicking the mouse button on specified nodes within the graphics window.

Usage

snip.rpart(x, toss)

Arguments

x                      fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function.

toss                    an integer vector containing indices (node numbers) of all subtrees to be snipped off. If missing, user selects branches to snip off as described below.

Details

A dendrogram of rpart is expected to be visible on the graphics device, and a graphics input device (e.g., a mouse) is required. Clicking (the selection button) on a node displays the node number, sample size, response y-value, and Error (dev). Clicking a second time on the same node snips that subtree off and visually erases the subtree. This process may be repeated an number of times. Warnings result from selecting the root or leaf nodes. Clicking the exit button will stop the snipping process and return the resulting rpart object.

See the documentation for the specific graphics device for details on graphical input techniques.

**Value**

A `rpart` object containing the nodes that remain after specified or selected subtrees have been snipped off.

**Warning**

Visually erasing the plot is done by over-plotting with the background colour. This will do nothing if the background is transparent (often true for screen devices).

**See Also**

[plot.rpart](#)

**Examples**

```
## dataset not in R
## Not run:
z.survey <- rpart(market.survey) # grow the rpart object
plot(z.survey) # plot the tree
z.survey2 <- snip.rpart(z.survey, toss = 2) # trim subtree at node 2
plot(z.survey2) # plot new tree

# can also interactively select the node using the mouse in the
# graphics window

## End(Not run)
```

---

solder

*Soldering of Components on Printed-Circuit Boards*

---

**Description**

The solder data frame has 720 rows and 6 columns, representing a balanced subset of a designed experiment varying 5 factors on the soldering of components on printed-circuit boards.

**Usage**

```
solder
```

**Format**

This data frame contains the following columns:

Opening a factor with levels ‘L’, ‘M’ and ‘S’ indicating the amount of clearance around the mounting pad.

Solder a factor with levels ‘Thick’ and ‘Thin’ giving the thickness of the solder used.

Mask a factor with levels ‘A1.5’, ‘A3’, ‘B3’ and ‘B6’ indicating the type and thickness of mask used.

PadType a factor with levels ‘D4’, ‘D6’, ‘D7’, ‘L4’, ‘L6’, ‘L7’, ‘L8’, ‘L9’, ‘W4’ and ‘W9’ giving the size and geometry of the mounting pad.

Panel 1:3 indicating the panel on a board being tested.

skips a numeric vector giving the number of visible solder skips.

**Source**

John M. Chambers and Trevor J. Hastie eds. (1992) *Statistical Models in S*, Wadsworth and Brooks/Cole, Pacific Grove, CA.

**Examples**

```
fit <- rpart(skips ~ Opening + Solder + Mask + PadType + Panel,
             data = solder, method = "anova")
summary(residuals(fit))
plot(predict(fit), residuals(fit))
```

---

stagec

---

*Stage C Prostate Cancer*

---

**Description**

A set of 146 patients with stage C prostate cancer, from a study exploring the prognostic value of flow cytometry.

**Usage**

```
data(stagec)
```

**Format**

A data frame with 146 observations on the following 8 variables.

pgtime Time to progression or last follow-up (years)

pgstat 1 = progression observed, 0 = censored

age age in years

eet early endocrine therapy, 1 = no, 2 = yes

g2 percent of cells in G2 phase, as found by flow cytometry

grade grade of the tumor, Farrow system

gleason grade of the tumor, Gleason system

ploidy the ploidy status of the tumor, from flow cytometry. Values are ‘diploid’, ‘tetraploid’, and ‘aneuploid’

**Details**

A tumor is called diploid (normal complement of dividing cells) if the fraction of cells in G2 phase was determined to be 13% or less. Aneuploid cells have a measurable fraction with a chromosome count that is neither 24 nor 48, for these the G2 percent is difficult or impossible to measure.

**Examples**

```
require(survival)
rpart(Surv(pgtime, pgstat) ~ ., stagec)
```

---

`summary.rpart`*Summarize a Fitted Rpart Object*

---

## Description

Returns a detailed listing of a fitted `rpart` object.

## Usage

```
## S3 method for class 'rpart'
summary(object, cp = 0, digits = getOption("digits"), file, ...)
```

## Arguments

|                     |   |
|---------------------|---|
| <code>object</code> | fitted model object of class <code>"rpart"</code> . This is assumed to be the result of some function that produces an object with the same named components as that returned by the <code>rpart</code> function. |
| <code>digits</code> | Number of significant digits to be used in the result.  |
| <code>cp</code>     | trim nodes with a complexity of less than <code>cp</code> from the listing.   |
| <code>file</code>   | write the output to a given file name. (Full listings of a tree are often quite long).  |
| <code>...</code>    | arguments to be passed to or from other methods.  |

## Details

This function is a method for the generic function `summary` for class `"rpart"`. It can be invoked by calling `summary` for an object of the appropriate class, or directly by calling `summary.rpart` regardless of the class of the object.

It prints the call, the table shown by [printcp](#), the variable importance (summing to 100) and details for each node (the details depending on the type of tree).

## See Also

[summary](#), [rpart.object](#), [printcp](#).

## Examples

```
## a regression tree
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
summary(z.auto)

## a classification tree with multiple variables and surrogate splits.
summary(rpart(Kyphosis ~ Age + Number + Start, data = kyphosis))
```

text.rpart

*Place Text on a Dendrogram Plot***Description**

Labels the current plot of the tree dendrogram with text.

**Usage**

```
## S3 method for class 'rpart'
text(x, splits = TRUE, label, FUN = text, all = FALSE,
     pretty = NULL, digits = getOption("digits") - 3, use.n = FALSE,
     fancy = FALSE, fwidth = 0.8, fheight = 0.8, bg = par("bg"),
     minlength = 1L, ...)
```

**Arguments**

|           |   |
|-----------|---|
| x         | fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function.  |
| splits    | logical flag. If TRUE (default), then the splits in the tree are labeled with the criterion for the split.  |
| label     | For compatibility with rpart2, ignored in this version (with a warning).  |
| FUN       | the name of a labeling function, e.g. text.   |
| all       | Logical. If TRUE, all nodes are labeled, otherwise just terminal nodes.   |
| minlength | the length to use for factor labels. A value of 1 causes them to be printed as 'a', 'b', .... Larger values use abbreviations of the label names. See the labels.rpart function for details.  |
| pretty    | an alternative to the minlength argument, see <a href="#">labels.rpart</a> .  |
| digits    | number of significant digits to include in numerical labels.  |
| use.n     | Logical. If TRUE, adds to label (\#events level1/\#events level2/etc. for class, n for anova, and \#events/n for poisson and exp).  |
| fancy     | Logical. If TRUE, nodes are represented by ellipses (interior nodes) and rectangles (leaves) and labeled by yval. The edges connecting the nodes are labeled by left and right splits.  |
| fwidth    | Relates to option fancy and the width of the ellipses and rectangles. If fwidth < 1 then it is a scaling factor (default = 0.8). If fwidth > 1 then it represents the number of character widths (for current graphical device) to use.     |
| fheight   | Relates to option fancy and the height of the ellipses and rectangles. If fheight < 1 then it is a scaling factor (default = 0.8). If fheight > 1 then it represents the number of character heights (for current graphical device) to use. |
| bg        | The color used to paint the background to annotations if fancy = TRUE.  |
| ...       | Graphical parameters may also be supplied as arguments to this function (see par). As labels often extend outside the plot region it can be helpful to specify xpd = TRUE.  |

Side Effects

the current plot of a tree dendrogram is labeled.

See Also

[text](#), [plot.rpart](#), [rpart](#), [labels.rpart](#), [abbreviate](#)

Examples

```
freen.tr <- rpart(y ~ ., freeny)
par(xpd = TRUE)
plot(freen.tr)
text(freen.tr, use.n = TRUE, all = TRUE)
```

---

|             |   |
|-------------|---|
| xpred.rpart | <i>Return Cross-Validated Predictions</i> |
|-------------|---|

---

Description

Gives the predicted values for an `rpart` fit, under cross validation, for a set of complexity parameter values.

Usage

```
xpred.rpart(fit, xval = 10, cp, return.all = FALSE)
```

Arguments

|                         |   |
|-------------------------|---|
| <code>fit</code>        | a object of class "rpart".  |
| <code>xval</code>       | number of cross-validation groups. This may also be an explicit list of integers that define the cross-validation groups. |
| <code>cp</code>         | the desired list of complexity values. By default it is taken from the <code>cptable</code> component of the fit.         |
| <code>return.all</code> | if <code>FALSE</code> return only the first element of the prediction   |

Details

Complexity penalties are actually ranges, not values. If the `cp` values found in the table were .36, .28, and .13, for instance, this means that the first row of the table holds for all complexity penalties in the range [.36, 1], the second row for `cp` in the range [.28, .36) and the third row for [.13, .28). By default, the geometric mean of each interval is used for cross validation.

Value

A matrix with one row for each observation and one column for each complexity value. If `return.all` is `TRUE` and the prediction for each node is a vector, then the result will be an array containing all of the predictions. When the response is categorical, for instance, the result contains the predicted class followed by the class probabilities of the selected terminal node; `result[1, , ]` will be the matrix of predicted classes, `result[2, , ]` the matrix of class 1 probabilities, etc.

**See Also**[rpart](#)**Examples**

```
fit <- rpart(Mileage ~ Weight, car.test.frame)
xmat <- xpred.rpart(fit)
xerr <- (xmat - car.test.frame$Mileage)^2
apply(xerr, 2, sum) # cross-validated error estimate

# approx same result as rel. error from printcp(fit)
apply(xerr, 2, sum)/var(car.test.frame$Mileage)
printcp(fit)
```

## Chapter 28

# The spatial package

---

`anova.trls`

*Anova tables for fitted trend surface objects*

---

### Description

Compute analysis of variance tables for one or more fitted trend surface model objects; where `anova.trls` is called with multiple objects, it passes on the arguments to `anovalist.trls`.

### Usage

```
## S3 method for class 'trls'
anova(object, ...)
anovalist.trls(object, ...)
```

### Arguments

|                     |   |
|---------------------|---|
| <code>object</code> | A fitted trend surface model object from <code>surf.ls</code> |
| <code>...</code>    | Further objects of the same kind                              |

### Value

`anova.trls` and `anovalist.trls` return objects corresponding to their printed tabular output.

### References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

data(topo, package="MASS")
topo0 <- surf.ls(0, topo)
topo1 <- surf.ls(1, topo)
topo2 <- surf.ls(2, topo)
topo3 <- surf.ls(3, topo)
topo4 <- surf.ls(4, topo)
anova(topo0, topo1, topo2, topo3, topo4)
summary(topo4)
```

---

|             |                                     |
|-------------|-------------------------------------|
| correlogram | <i>Compute Spatial Correlograms</i> |
|-------------|-------------------------------------|

---

**Description**

Compute spatial correlograms of spatial data or residuals.

**Usage**

```
correlogram(krig, nint, plotit = TRUE, ...)
```

**Arguments**

|        |  |
|--------|--|
| krig   | trend-surface or kriging object with columns x, y, and z |
| nint   | number of bins used                                      |
| plotit | logical for plotting                                     |
| ...    | parameters for the plot                                  |

**Details**

Divides range of data into nint bins, and computes the covariance for pairs with separation in each bin, then divides by the variance. Returns results for bins with 6 or more pairs.

**Value**

x and y coordinates of the correlogram, and cnt, the number of pairs averaged per bin.

**Side Effects**

Plots the correlogram if plotit = TRUE.

```

---

expcov

*Spatial Covariance Functions*

---

**Description**

Spatial covariance functions for use with `surf.gls`.

**Usage**

```
expcov(r, d, alpha = 0, se = 1)
gaucov(r, d, alpha = 0, se = 1)
sphercov(r, d, alpha = 0, se = 1, D = 2)
```

**Arguments**

|       |   |
|-------|---|
| r     | vector of distances at which to evaluate the covariance |
| d     | range parameter   |
| alpha | proportion of nugget effect                             |
| se    | standard deviation at distance zero                     |
| D     | dimension of spheres.                                   |

**Value**

vector of covariance values.

Kaver

Average *K*-functions from Simulations

---

## Description

Forms the average of a series of (usually simulated) *K*-functions.

## Usage

```
Kaver(fs, nsim, ...)
```

## Arguments

|      |  |
|------|--|
| fs   | full scale for <i>K</i> -fn                    |
| nsim | number of simulations                          |
| ...  | arguments to simulate one point process object |

## Value

list with components *x* and *y* of the average *K*-fn on *L*-scale.

## References

Ripley, B. D. (1981) *Spatial Statistics*. Wiley.

| Kfn | <i>Compute K-fn of a Point Pattern</i> |
|-----|--|

---

**Description**

Actually computes  $L = \sqrt{K/\pi}$ .

**Usage**

```
Kfn(pp, fs, k=100)
```

**Arguments**

|    |  |
|----|--|
| pp | a list such as a pp object, including components x and y |
| fs | full scale of the plot                                   |
| k  | number of regularly spaced distances in (0, fs)          |

**Details**

relies on the domain D having been set by ppinit or ppreion.

**Value**

A list with components

|      |  |
|------|--|
| x    | vector of distances  |
| y    | vector of L-fn values  |
| k    | number of distances returned – may be less than k if fs is too large |
| dmin | minimum distance between pair of points                              |
| lm   | maximum deviation from $L(t) = t$                                    |

ppinit

*Read a Point Process Object from a File***Description**

Read a file in standard format and create a point process object.

**Usage**

```
ppinit(file)
```

**Arguments**

`file`                      string giving file name

**Details**

The file should contain  
the number of points  
a header (ignored)  
`x1 xu y1 yu scale`  
`x y` (repeated `n` times)

**Value**

class "pp" object with components `x`, `y`, `x1`, `xu`, `y1`, `yu`

**Side Effects**

Calls ppregion to set the domain.

predict.trls

---

Predict method for trend surface fits

---

**Description**

Predicted values based on trend surface model object

**Usage**

```
## S3 method for class 'trls'
predict(object, x, y, ...)
```

**Arguments**

|        |  |
|--------|--|
| object | Fitted trend surface model object returned by <code>surf.ls</code> |
| x      | Vector of prediction location eastings (x coordinates)             |
| y      | Vector of prediction location northings (y coordinates)            |
| ...    | further arguments passed to or from other methods.                 |

**Value**

`predict.trls` produces a vector of predictions corresponding to the prediction locations. To display the output with image or contour, use `trmat` or convert the returned vector to matrix form.

**References**

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

contour(prsurf, levels=seq(700, 925, 25))
```

---

Psim

---

*Simulate Binomial Spatial Point Process*

---

**Description**

Simulate Binomial spatial point process.

**Usage**

```
Psim(n)
```

**Arguments**

n                      number of points

**Details**

relies on the region being set by `ppinit` or `ppregion`.

**Value**

list of vectors of x and y coordinates.

**Side Effects**

uses the random number generator.

---

|       |  |
|-------|--|
| semat | <i>Evaluate Kriging Standard Error of Prediction over a Grid</i> |
|-------|--|

---

**Description**

Evaluate Kriging standard error of prediction over a grid.

**Usage**

```
semat(obj, xl, xu, yl, yu, n, se)
```

**Arguments**

|     |   |
|-----|---|
| obj | object returned by <code>surf.gls</code>  |
| xl  | limits of the rectangle for grid  |
| xu  |   |
| yl  |   |
| yu  |   |
| n   | use $n \times n$ grid within the rectangle  |
| se  | standard error at distance zero as a multiple of the supplied covariance. Otherwise estimated, and it assumed that a correlation function was supplied. |

**Value**

list with components x, y and z suitable for contour and image.

**References**

```

---

**SSI***Simulates Sequential Spatial Inhibition Point Process*

---

**Description**

Simulates SSI (sequential spatial inhibition) point process.

**Usage**

```
SSI(n, r)
```

**Arguments**

|   |                     |
|---|---------------------|
| n | number of points    |
| r | inhibition distance |

**Details**

uses the region set by ppinit or ppreion.

**Value**

list of vectors of x and y coordinates

**Side Effects**

uses the random number generator.

**Warnings**

will never return if r is too large and it cannot place n points.

**References**

lines(Kaver(10, 25, SSI(69, 1.2)))
```

---

 Strauss

*Simulates Strauss Spatial Point Process*

---

**Description**

Simulates Strauss spatial point process.

**Usage**

```
Strauss(n, c=0, r)
```

**Arguments**

|   |   |
|---|---|
| n | number of points  |
| c | parameter $c$ in $[0, 1]$ . $c = 0$ corresponds to complete inhibition at distances up to $r$ . |
| r | inhibition distance   |

**Details**

Uses spatial birth-and-death process for  $4n$  steps, or for  $40n$  steps starting from a binomial pattern on the first call from an other function. Uses the region set by `ppinit` or `ppregion`.

**Value**

list of vectors of  $x$  and  $y$  coordinates

**Side Effects**

uses the random number generator

**References**

surf.gls

*Fits a Trend Surface by Generalized Least-squares***Description**

Fits a trend surface by generalized least-squares.

**Usage**

```
surf.gls(np, covmod, x, y, z, nx = 1000, ...)
```

**Arguments**

|        |   |
|--------|---|
| np     | degree of polynomial surface  |
| covmod | function to evaluate covariance or correlation function   |
| x      | x coordinates or a data frame with columns x, y, z  |
| y      | y coordinates   |
| z      | z coordinates. Will supersede x\$z  |
| nx     | Number of bins for table of the covariance. Increasing adds accuracy, and increases size of the object. |
| ...    | parameters for covmod   |

**Value**

list with components

|      |                                   |
|------|-----------------------------------|
| beta | the coefficients                  |
| x    |                                   |
| y    |                                   |
| z    | and others for internal use only. |

trls.influence

Regression diagnostics for trend surfaces

---

## Description

This function provides the basic quantities which are used in forming a variety of diagnostics for checking the quality of regression fits for trend surfaces calculated by `surf.ls`.

## Usage

```
trls.influence(object)
## S3 method for class 'trls'
plot(x, border = "red", col = NA, pch = 4, cex = 0.6,
     add = FALSE, div = 8, ...)
```

## Arguments

|   |   |
|---|---|
| <code>object, x</code>                  | Fitted trend surface model from <code>surf.ls</code>                |
| <code>div</code>                        | scaling factor for influence circle radii in <code>plot.trls</code> |
| <code>add</code>                        | add influence plot to existing graphics if TRUE                     |
| <code>border, col, pch, cex, ...</code> | additional graphical parameters                                     |

## Value

`trls.influence` returns a list with components:

|                      |   |
|----------------------|---|
| <code>r</code>       | raw residuals as given by <code>residuals.trls</code> |
| <code>hii</code>     | diagonal elements of the Hat matrix                   |
| <code>stresid</code> | standardised residuals                                |
| <code>Di</code>      | Cook's statistic                                      |

variogram

*Compute Spatial Variogram***Description**

Compute spatial (semi-)variogram of spatial data or residuals.

**Usage**

```
variogram(krig, nint, plotit = TRUE, ...)
```

**Arguments**

|        |  |
|--------|--|
| krig   | trend-surface or kriging object with columns x, y, and z |
| nint   | number of bins used                                      |
| plotit | logical for plotting                                     |
| ...    | parameters for the plot                                  |

**Details**

Divides range of data into nint bins, and computes the average squared difference for pairs with separation in each bin. Returns results for bins with 6 or more pairs.

**Value**

x and y coordinates of the variogram and cnt, the number of pairs averaged per bin.

**Side Effects**

Plots the variogram if plotit = TRUE

## Chapter 29

# The survival package

---

aareg

*Aalen's additive regression model for censored data*

---

### Description

Returns an object of class "aareg" that represents an Aalen model.

### Usage

```
aareg(formula, data, weights, subset, na.action,
      qrtol=1e-07, nmin, dfbeta=FALSE, taper=1,
      test = c('aalen', 'variance', 'nrisk'),
      model=FALSE, x=FALSE, y=FALSE)
```

### Arguments

|         |  |
|---------|--|
| formula | a formula object, with the response on the left of a '~' operator and the terms, separated by + operators, on the right. The response must be a Surv object. Due to a particular computational approach that is used, the model MUST include an intercept term. If "-1" is used in the model formula the program will ignore it.   |
| data    | data frame in which to interpret the variables named in the formula, subset, and weights arguments. This may also be a single number to handle some special cases – see below for details. If data is missing, the variables in the model formula should be in the search path.  |
| weights | vector of observation weights. If supplied, the fitting algorithm minimizes the sum of the weights multiplied by the squared residuals (see below for additional technical details). The length of weights must be the same as the number of observations. The weights must be nonnegative and it is recommended that they be strictly positive, since zero weights are ambiguous. To exclude particular observations from the model, use the subset argument instead of zero weights. |
| subset  | expression specifying which subset of observations should be used in the fit. This can be a logical vector (which is replicated to have length equal to the number of observations), a numeric vector indicating the observation numbers to be included, or a character vector of the observation names that should be included. All observations are included by default.   |

|                          |  |
|--------------------------|--|
| <code>na.action</code>   | a function to filter missing data. This is applied to the <code>model.frame</code> after any subset argument has been applied. The default is <code>na.fail</code> , which returns an error if any missing values are found. An alternative is <code>na.exclude</code> , which deletes observations that contain one or more missing values.   |
| <code>qrtol</code>       | tolerance for detection of singularity in the QR decomposition   |
| <code>nmin</code>        | minimum number of observations for an estimate; defaults to 3 times the number of covariates. This essentially truncates the computations near the tail of the data set, when <code>n</code> is small and the calculations can become numerically unstable.  |
| <code>dfbeta</code>      | should the array of <code>dfbeta</code> residuals be computed. This implies computation of the sandwich variance estimate. The residuals will always be computed if there is a <code>cluster</code> term in the model formula.   |
| <code>taper</code>       | allows for a smoothed variance estimate. $\text{Var}(x)$ , where <code>x</code> is the set of covariates, is an important component of the calculations for the Aalen regression model. At any given time point <code>t</code> , it is computed over all subjects who are still at risk at time <code>t</code> . The <code>taper</code> argument allows smoothing these estimates, for example <code>taper=(1:4)/4</code> would cause the variance estimate used at any event time to be a weighted average of the estimated variance matrices at the last 4 death times, with a weight of 1 for the current death time and decreasing to 1/4 for prior event times. The default value gives the standard Aalen model. |
| <code>test</code>        | selects the weighting to be used, for computing an overall “average” coefficient vector over time and the subsequent test for equality to zero.  |
| <code>model, x, y</code> | should copies of the model frame, the <code>x</code> matrix of predictors, or the response vector <code>y</code> be included in the saved result.  |

## Details

The Aalen model assumes that the cumulative hazard  $H(t)$  for a subject can be expressed as  $a(t) + X B(t)$ , where  $a(t)$  is a time-dependent intercept term,  $X$  is the vector of covariates for the subject (possibly time-dependent), and  $B(t)$  is a time-dependent matrix of coefficients. The estimates are inherently non-parametric; a fit of the model will normally be followed by one or more plots of the estimates.

The estimates may become unstable near the tail of a data set, since the increment to  $B$  at time `t` is based on the subjects still at risk at time `t`. The tolerance and/or `nmin` parameters may act to truncate the estimate before the last death. The `taper` argument can also be used to smooth out the tail of the curve. In practice, the addition of a taper such as 1:10 appears to have little effect on death times when `n` is still reasonably large, but can considerably dampen wild oscillations in the tail of the plot.

## Value

an object of class “aareg” representing the fit, with the following components:

|                             |  |
|-----------------------------|--|
| <code>n</code>              | vector containing the number of observations in the data set, the number of event times, and the number of event times used in the computation |
| <code>times</code>          | vector of sorted event times, which may contain duplicates   |
| <code>nrisk</code>          | vector containing the number of subjects at risk, of the same length as <code>times</code>   |
| <code>coefficient</code>    | matrix of coefficients, with one row per event and one column per covariate  |
| <code>test.statistic</code> | the value of the test statistic, a vector with one element per covariate   |
| <code>test.var</code>       | variance-covariance matrix for the test  |
| <code>test</code>           | the type of test; a copy of the <code>test</code> argument above   |
| <code>tweight</code>        | matrix of weights used in the computation, one row per event   |
| <code>call</code>           | a copy of the call that produced this result   |

```

---

aeqSurv

*Adjudicate near ties in a Surv object*

---

## Description

The check for tied survival times can fail due to floating point imprecision, which can make actual ties appear to be distinct values. Routines that depend on correct identification of ties pairs will then give incorrect results, e.g., a Cox model. This function rectifies these.

## Usage

```
aeqSurv(x, tolerance = sqrt(.Machine$double.eps))
```

## Arguments

|           |   |
|-----------|---|
| x         | a Surv object   |
| tolerance | the tolerance used to detect values that will be considered equal |

## Details

This routine is called by both `survfit` and `coxph` to deal with the issue of ties that get incorrectly broken due to floating point imprecision. See the short vignette on tied times for a simple example. Use the `timefix` argument of `survfit` or `coxph.control` to control the option if desired.

The rule for ‘equality’ is identical to that used by the `all.equal` routine. Pairs of values that are within round off error of each other are replaced by the smaller value. An error message is generated if this process causes a 0 length time interval to be created.

## Value

a Surv object identical to the original, but with ties restored.

## Author(s)

Terry Therneau

## See Also

[survfit](#), [coxph.control](#)

---

agreg.fit*Cox model fitting functions*

---

## Description

These are the the functions called by `coxph` that do the actual computation. In certain situations, e.g. a simulation, it may be advantageous to call these directly rather than the usual `coxph` call using a model formula.

## Usage

```
agreg.fit(x, y, strata, offset, init, control, weights, method, rownames)
coxph.fit(x, y, strata, offset, init, control, weights, method, rownames)
```

## Arguments

|                       |  |
|-----------------------|--|
| <code>x</code>        | Matix of predictors. This should <i>not</i> include an intercept.  |
| <code>y</code>        | a <code>Surv</code> object containing either 2 columns ( <code>coxph.fit</code> ) or 3 columns ( <code>agreg.fit</code> ). |
| <code>strata</code>   | a vector containing the stratification, or <code>NULL</code>   |
| <code>offset</code>   | optional offset vector   |
| <code>init</code>     | initial values for the coefficients  |
| <code>control</code>  | the result of a call to <code>coxph.control</code>   |
| <code>weights</code>  | optional vector of weights   |
| <code>method</code>   | method for hanling ties, one of "breslow" or "efron"   |
| <code>rownames</code> | this is only needed for a <code>NULL</code> model, in which case it contains the rownames (if any) of the original data.   |

## Details

This routine does no checking that arguments are the proper length or type. Only use it if you know what you are doing!

## Value

a list containing results of the fit

## Author(s)

Terry Therneau

| aml | <i>Acute Myelogenous Leukemia survival data</i> |
|-----|---|

---

**Description**

Survival in patients with Acute Myelogenous Leukemia. The question at the time was whether the standard course of chemotherapy should be extended ('maintenance') for additional cycles.

**Usage**

```
aml  
leukemia
```

**Format**

```
time:  survival or censoring time  
status: censoring status  
x:     maintenance chemotherapy given? (factor)
```

**Source**

Rupert G. Miller (1997), *Survival Analysis*. John Wiley & Sons. ISBN: 0-471-25218-2.

---

|             |  |
|-------------|--|
| anova.coxph | <i>Analysis of Deviance for a Cox model.</i> |
|-------------|--|

---

**Description**

Compute an analysis of deviance table for one or more Cox model fits.

**Usage**

```
## S3 method for class 'coxph'  
anova(object, ..., test = 'Chisq')
```

**Arguments**

|        |  |
|--------|--|
| object | An object of class coxph   |
| ...    | Further coxph objects  |
| test   | a character string. The appropriate test is a chisquare, all other choices result in no test being done. |

## Details

Specifying a single object gives a sequential analysis of deviance table for that fit. That is, the reductions in the model log-likelihood as each term of the formula is added in turn are given in as the rows of a table, plus the log-likelihoods themselves. A robust variance estimate is normally used in situations where the model may be mis-specified, e.g., multiple events per subject. In this case a comparison of partial-likelihood values does not make sense, and anova will refuse to print results.

If more than one object is specified, the table has a row for the degrees of freedom and loglikelihood for each model. For all but the first model, the change in degrees of freedom and loglik is also given. (This only make statistical sense if the models are nested.) It is conventional to list the models from smallest to largest, but this is up to the user.

The table will optionally contain test statistics (and P values) comparing the reduction in loglik for each row.

## Value

An object of class "anova" inheriting from class "data.frame".

## Warning

The comparison between two or more models by anova or will only be valid if they are fitted to the same dataset. This may be a problem if there are missing values.

## See Also

[coxph](#), [anova](#).

## Examples

```
fit <- coxph(Surv(futime, fustat) ~ resid.ds *rx + ecog.ps, data = ovarian)
anova(fit)
fit2 <- coxph(Surv(futime, fustat) ~ resid.ds +rx + ecog.ps, data=ovarian)
anova(fit2,fit)
```

---

attrassign

*Create new-style "assign" attribute*

---

## Description

The "assign" attribute on model matrices describes which columns come from which terms in the model formula. It has two versions. R uses the original version, but the alternate version found in S-plus is sometimes useful.

## Usage

```
## Default S3 method:
attrassign(object, tt,...)
## S3 method for class 'lm'
attrassign(object,...)
```

**Arguments**

|        |                                     |
|--------|-------------------------------------|
| object | model matrix or linear model object |
| tt     | terms object                        |
| ...    | ignored                             |

**Details**

For instance consider the following

```
survreg(Surv(time, status) ~ age + sex + factor(ph.ecog), lung)
```

R gives the compact for for assign, a vector (0, 1, 2, 3, 3, 3); which can be read as “the first column of the X matrix (intercept) goes with none of the terms, the second column of X goes with term 1 of the model equation, the third column of X with term 2, and columns 4-6 with term 3”.

The alternate (S-Plus default) form is a list

```
$(Intercept)    1
$age             2
$sex             3
$factor(ph.ecog) 4 5 6
```

**Value**

A list with names corresponding to the term names and elements that are vectors indicating which columns come from which terms

**See Also**

[terms,model.matrix](#)

**Examples**

```
formula <- Surv(time,status)~factor(ph.ecog)
tt <- terms(formula)
mf <- model.frame(tt,data=lung)
mm <- model.matrix(tt,mf)
## a few rows of data
mm[1:3,]
## old-style assign attribute
attr(mm,"assign")
## alternate style assign attribute
attrassign(mm,tt)
```

---

|         |                                       |
|---------|---------------------------------------|
| basehaz | <i>Alias for the survfit function</i> |
|---------|---------------------------------------|

---

## Description

Compute the predicted survival curve for a Cox model.

## Usage

```
basehaz(fit, centered=TRUE)
```

## Arguments

|          |  |
|----------|--|
| fit      | a coxph fit  |
| centered | if TRUE return data from a predicted survival curve at the mean values of the covariates <code>fit\$mean</code> , if FALSE return a prediction for all covariates equal to zero. |

## Details

This function is simply an alias for `survfit`, which is the actual function that does all the computations. See the manual page for that function for the preferred use. This function survives only for backwards support of prior usage.

The function returns a data frame containing the `time`, `cumhaz` and optionally the `strata` (if the fitted Cox model used a `strata` statement), which are copied the `survfit` result. If there are factor variables in the model, then the default predictions at the "mean" are meaningless since they do not correspond to any possible subject; correct results require use of the `newdata` argument of `survfit`. Results for all covariates =0 are normally only of use as a building block for further calculations.

## Value

a data frame with variable names of `hazard`, `time` and optionally `strata`. The first is actually the cumulative hazard.

|---------|-----------------------------------|
| bladder | <i>Bladder Cancer Recurrences</i> |
|---------|-----------------------------------|

---

## Description

Data on recurrences of bladder cancer, used by many people to demonstrate methodology for recurrent event modelling.

Bladder1 is the full data set from the study. It contains all three treatment arms and all recurrences for 118 subjects; the maximum observed number of recurrences is 9.

Bladder is the data set that appears most commonly in the literature. It uses only the 85 subjects with nonzero follow-up who were assigned to either thiotepa or placebo, and only the first four recurrences for any patient. The status variable is 1 for recurrence and 0 for everything else (including death for any reason). The data set is laid out in the competing risks format of the paper by Wei, Lin, and Weissfeld.

Bladder2 uses the same subset of subjects as bladder, but formatted in the (start, stop] or Anderson-Gill style. Note that in transforming from the WLW to the AG style data set there is a quite common programming mistake that leads to extra follow-up time for 12 subjects: all those with follow-up beyond their 4th recurrence. This "follow-up" is a side effect of throwing away all events after the fourth while retaining the last follow-up time variable from the original data. The bladder2 data set found here does not make this mistake, but some analyses in the literature have done so; it results in the addition of a small amount of immortal time bias and shrinks the fitted coefficients towards zero.

## Usage

```
bladder1
bladder
bladder2
```

|     |   |
|-----|---|
| cch | <i>Fits proportional hazards regression model to case-cohort data</i> |
|-----|---|

---

Description

Returns estimates and standard errors from relative risk regression fit to data from case-cohort studies. A choice is available among the Prentice, Self-Prentice and Lin-Ying methods for unstratified data. For stratified data the choice is between Borgan I, a generalization of the Self-Prentice estimator for unstratified case-cohort data, and Borgan II, a generalization of the Lin-Ying estimator.

Usage

```
cch(formula, data = sys.parent(), subcoh, id, stratum=NULL, cohort.size,
    method =c("Prentice","SelfPrentice","LinYing","I.Borgan","II.Borgan"),
    robust=FALSE)
```

Arguments

|             |   |
|-------------|---|
| formula     | A formula object that must have a <a href="#">Surv</a> object as the response. The Surv object must be of type "right", or of type "counting".  |
| subcoh      | Vector of indicators for subjects sampled as part of the sub-cohort. Code 1 or TRUE for members of the sub-cohort, 0 or FALSE for others. If data is a data frame then subcoh may be a one-sided formula. |
| id          | Vector of unique identifiers, or formula specifying such a vector.  |
| stratum     | A vector of stratum indicators or a formula specifying such a vector  |
| cohort.size | Vector with size of each stratum original cohort from which subcohort was sampled   |
| data        | An optional data frame in which to interpret the variables occurring in the formula.  |
| method      | Three procedures are available. The default method is "Prentice", with options for "SelfPrentice" or "LinYing".   |
| robust      | For "LinYing" only, if robust=TRUE, use design-based standard errors even for phase I   |

## Details

Implements methods for case-cohort data analysis described by Therneau and Li (1999). The three methods differ in the choice of "risk sets" used to compare the covariate values of the failure with those of others at risk at the time of failure. "Prentice" uses the sub-cohort members "at risk" plus the failure if that occurs outside the sub-cohort and is score unbiased. "SelfPren" (Self-Prentice) uses just the sub-cohort members "at risk". These two have the same asymptotic variance-covariance matrix. "LinYing" (Lin-Ying) uses the all members of the sub-cohort and all failures outside the sub-cohort who are "at risk". The methods also differ in the weights given to different score contributions.

The data argument must not have missing values for any variables in the model. There must not be any censored observations outside the subcohort.

## Value

An object of class "cch" incorporating a list of estimated regression coefficients and two estimates of their asymptotic variance-covariance matrix.

|           |   |
|-----------|---|
| coef      | regression coefficients.                              |
| naive.var | Self-Prentice model based variance-covariance matrix. |
| var       | Lin-Ying empirical variance-covariance matrix.        |

cgd

*Chronic Granulomatous Disease data***Description**

Data are from a placebo controlled trial of gamma interferon in chronic granulomatous disease (CGD). Contains the data on time to serious infections observed through end of study for each patient.

**Usage**

cgd

**Format**

**id** subject identification number

**center** enrolling center

**random** date of randomization  
**treatment** placebo or gamma interferon  
**sex** sex  
**age** age in years, at study entry  
**height** height in cm at study entry  
**weight** weight in kg at study entry  
**inherit** pattern of inheritance  
**steroids** use of steroids at study entry, 1=yes  
**propylac** use of prophylactic antibiotics at study entry  
**hos.cat** a categorization of the centers into 4 groups  
**tstart, tstop** start and end of each time interval  
**status** 1=the interval ends with an infection  
**enum** observation number within subject

### Details

The cgd0 data set is in the form found in the references, with one line per patient and no recoding of the variables. The cgd data set (this one) has been cast into (start, stop] format with one line per event, and covariates such as center recoded as factors to include meaningful labels.

[cgd](#)

---

|           |  |
|-----------|--|
| cipoisson | <i>Confidence limits for the Poisson</i> |
|-----------|--|

---

**Description**

Confidence interval calculation for Poisson rates.

**Usage**

```
cipoisson(k, time = 1, p = 0.95, method = c("exact", "anscombe"))
```

**Arguments**

- |        |  |
|--------|--|
| k      | Number of successes                            |
| time   | Total time on trial                            |
| p      | Probability level for the (two-sided) interval |
| method | The method for computing the interval.         |

## Details

The likelihood method is based on equation 10.10 of Feller, which relates poisson probabilities to tail area of the gamma distribution. The Anscombe approximation is based on the fact that  $\sqrt{k + 3/8}$  has a nearly constant variance of  $1/4$ , along with a continuity correction.

There are many other proposed intervals: Patil and Kulkarni list and evaluate 19 different suggestions from the literature!. The exact intervals can be overly broad for very small values of  $k$ , many of the other approaches try to shrink the lengths, with varying success.

## Value

a vector, matrix, or array. If both  $k$  and  $time$  are single values the result is a vector of length 2 containing the lower and upper limits. If either or both are vectors the result is a matrix with two columns. If  $k$  is a matrix or array, the result will be an array with one more dimension; in this case the dimensions and dimnames (if any) of  $k$  are preserved.

---

clogit

---

*Conditional logistic regression*

---

## Description

Estimates a logistic regression model by maximising the conditional likelihood. Uses a model formula of the form `case.status~exposure+strata(matched.set)`. The default is to use the exact conditional likelihood, a commonly used approximate conditional likelihood is provided for compatibility with older software.

**Usage**

```
clogit(formula, data, weights, subset, na.action,
       method=c("exact", "approximate", "efron", "breslow"),
       ...)
```

**Arguments**

|           |  |
|-----------|--|
| formula   | Model formula  |
| data      | data frame   |
| weights   | optional, names the variable containing case weights   |
| subset    | optional, subset the data  |
| na.action | optional na.action argument. By default the global option na.action is used.                   |
| method    | use the correct (exact) calculation in the conditional likelihood or one of the approximations |
| ...       | optional arguments, which will be passed to coxph.control                                      |

**Details**

It turns out that the loglikelihood for a conditional logistic regression model = loglik from a Cox model with a particular data structure. Proving this is a nice homework exercise for a PhD statistics class; not too hard, but the fact that it is true is surprising.

When a well tested Cox model routine is available many packages use this ‘trick’ rather than writing a new software routine from scratch, and this is what the clogit routine does. In detail, a stratified Cox model with each case/control group assigned to its own stratum, time set to a constant, status of 1=case 0=control, and using the exact partial likelihood has the same likelihood formula as a conditional logistic regression. The clogit routine creates the necessary dummy variable of times (all 1) and the strata, then calls coxph.

The computation of the exact partial likelihood can be very slow, however. If a particular strata had say 10 events out of 20 subjects we have to add up a denominator that involves all possible ways of choosing 10 out of 20, which is  $20!/(10! \ 10!) = 184756$  terms. Gail et al describe a fast recursion method which partly ameliorates this; it was incorporated into version 2.36-11 of the survival package. The computation remains infeasible for very large groups of ties, say 100 ties out of 500 subjects, and may even lead to integer overflow for the subscripts – in this latter case the routine will refuse to undertake the task. The Efron approximation is normally a sufficiently accurate substitute.

Most of the time conditional logistic modeling is applied data with 1 case + k controls per set, in which case all of the approximations for ties lead to exactly the same result. The ‘approximate’ option maps to the Breslow approximation for the Cox model, for historical reasons.

Case weights are not allowed when the exact option is used, as the likelihood is not defined for fractional weights. Even with integer case weights it is not clear how they should be handled. For instance if there are two deaths in a strata, one with weight=1 and one with weight=2, should the likelihood calculation consider all subsets of size 2 or all subsets of size 3? Consequently, case weights are ignored by the routine in this case.

**Value**

An object of class “clogit”, which is a wrapper for a “coxph” object.

cluster

*Identify clusters.*

---

## Description

This is a special function used in the context of survival models. It identifies correlated groups of observations, and is used on the right hand side of a formula. Using `cluster()` in a formula implies that robust sandwich variance estimators are desired.

## Usage

```
cluster(x)
```

## Arguments

x                      A character, factor, or numeric variable.

## Details

The function's only action is semantic, to mark a variable as the cluster indicator. The resulting variance is what is known as the "working independence" variance in a GEE model. Note that one cannot use both a frailty term and a cluster term in the same model, the first is a mixed-effects approach to correlation and the second a GEE approach, and these don't mix.

**Value**

x

**See Also**[coxph](#), [survreg](#)**Examples**

```

                        subset=(sex=='f'))
```

colon

*Chemotherapy for Stage B/C colon cancer***Description**

These are data from one of the first successful trials of adjuvant chemotherapy for colon cancer. Levamisole is a low-toxicity compound previously used to treat worm infestations in animals; 5-FU is a moderately toxic (as these things go) chemotherapy agent. There are two records per person, one for recurrence and one for death

**Usage**

colon

**Format**

|           |   |
|-----------|---|
| id:       | id  |
| study:    | 1 for all patients  |
| rx:       | Treatment - Obs(ervation), Lev(amisole), Lev(amisole)+5-FU                        |
| sex:      | 1=male  |
| age:      | in years  |
| obstruct: | obstruction of colon by tumour  |
| perfor:   | perforation of colon  |
| adhere:   | adherence to nearby organs  |
| nodes:    | number of lymph nodes with detectable cancer                                      |
| time:     | days until event or censoring   |
| status:   | censoring status  |
| differ:   | differentiation of tumour (1=well, 2=moderate, 3=poor)                            |
| extent:   | Extent of local spread (1=submucosa, 2=muscle, 3=serosa, 4=contiguous structures) |
| surg:     | time from surgery to registration (0=short, 1=long)                               |
| node4:    | more than 4 positive lymph nodes  |
| etype:    | event type: 1=recurrence,2=death  |

**Note**

The study is originally described in Laurie (1989). The main report is found in Moertel (1990). This data set is closest to that of the final report in Moertel (1991). A version of the data with less follow-up time was used in the paper by Lin (1994).

---

 cox.zph

---

*Test the Proportional Hazards Assumption of a Cox Regression*

---

**Description**

Test the proportional hazards assumption for a Cox regression model fit (coxph).

**Usage**

```
cox.zph(fit, transform="km", global=TRUE)
```

**Arguments**

|           |  |
|-----------|--|
| fit       | the result of fitting a Cox regression model, using the coxph function.  |
| transform | a character string specifying how the survival times should be transformed before the test is performed. Possible values are "km", "rank", "identity" or a function of one argument. |
| global    | should a global chi-square test be done, in addition to the per-variable tests.  |

**Value**

an object of class "cox.zph", with components:

|       |  |
|-------|--|
| table | a matrix with one row for each variable, and optionally a last row for the global test. Columns of the matrix contain the correlation coefficient between transformed survival time and the scaled Schoenfeld residuals, a chi-square, and the two-sided p-value. For the global test there is no appropriate correlation, so an NA is entered into the matrix as a placeholder. |
|-------|--|

|      |   |
|------|---|
| x    | the transformed time axis.  |
| y    | the matrix of scaled Schoenfeld residuals. There will be one column per variable and one row per event. The row labels contain the original event times (for the identity transform, these will be the same as x).  |
| call | the calling sequence for the routine.<br><br>The computations require the original x matrix of the Cox model fit. Thus it saves time if the x=TRUE option is used in coxph. This function would usually be followed by both a plot and a print of the result. The plot gives an estimate of the time-dependent coefficient $\beta(t)$ . If the proportional hazards assumption is true, $\beta(t)$ will be a horizontal line. The printout gives a test for $slope=0$ . |

print(temp)           # display the results
plot(temp)            # plot curves
```

---

coxph

*Fit Proportional Hazards Regression Model*

---

## Description

Fits a Cox proportional hazards regression model. Time dependent variables, time dependent strata, multiple events per subject, and other extensions are incorporated using the counting process formulation of Andersen and Gill.

## Usage

```
coxph(formula, data=, weights, subset,
      na.action, init, control,
      ties=c("efron", "breslow", "exact"),
      singular.ok=TRUE, robust=FALSE,
      model=FALSE, x=FALSE, y=TRUE, tt, method, ...)
```

## Arguments

|         |   |
|---------|---|
| formula | a formula object, with the response on the left of a ~ operator, and the terms on the right. The response must be a survival object as returned by the Surv function. |
|---------|---|

|                          |  |
|--------------------------|--|
| <code>data</code>        | a <code>data.frame</code> in which to interpret the variables named in the formula, or in the subset and the weights argument.   |
| <code>weights</code>     | vector of case weights. For a thorough discussion of these see the book by Therneau and Grambsch.  |
| <code>subset</code>      | expression indicating which subset of the rows of data should be used in the fit. All observations are included by default.  |
| <code>na.action</code>   | a missing-data filter function. This is applied to the <code>model.frame</code> after any subset argument has been used. Default is <code>options()\$na.action</code> .  |
| <code>init</code>        | vector of initial values of the iteration. Default initial value is zero for all variables.  |
| <code>control</code>     | Object of class <code>coxph.control</code> specifying iteration limit and other control options. Default is <code>coxph.control(...)</code> .  |
| <code>ties</code>        | a character string specifying the method for tie handling. If there are no tied death times all the methods are equivalent. Nearly all Cox regression programs use the Breslow method by default, but not this one. The Efron approximation is used as the default here, it is more accurate when dealing with tied death times, and is as efficient computationally. The “exact partial likelihood” is equivalent to a conditional logistic model, and is appropriate when the times are a small set of discrete values. See further below. |
| <code>singular.ok</code> | logical value indicating how to handle collinearity in the model matrix. If TRUE, the program will automatically skip over columns of the X matrix that are linear combinations of earlier columns. In this case the coefficients for such columns will be NA, and the variance matrix will contain zeros. For ancillary calculations, such as the linear predictor, the missing coefficients are treated as zeros.  |
| <code>robust</code>      | this argument has been deprecated, use a cluster term in the model instead. (The two options accomplish the same goal – creation of a robust variance – but the second is more flexible).  |
| <code>model</code>       | logical value: if TRUE, the model frame is returned in component <code>model</code> .  |
| <code>x</code>           | logical value: if TRUE, the x matrix is returned in component <code>x</code> .   |
| <code>y</code>           | logical value: if TRUE, the response vector is returned in component <code>y</code> .  |
| <code>tt</code>          | optional list of time-transform functions.   |
| <code>method</code>      | alternate name for the <code>ties</code> argument.   |
| <code>...</code>         | Other arguments will be passed to <code>coxph.control</code>   |

## Details

The proportional hazards model is usually expressed in terms of a single survival time value for each person, with possible censoring. Andersen and Gill reformulated the same problem as a counting process; as time marches onward we observe the events for a subject, rather like watching a Geiger counter. The data for a subject is presented as multiple rows or “observations”, each of which applies to an interval of observation (start, stop].

The routine internally scales and centers data to avoid overflow in the argument to the exponential function. These actions do not change the result, but lead to more numerical stability. However, arguments to offset are not scaled since there are situations where a large offset value is a purposefully used. Users should not use normally allow large numeric offset values.

## Value

an object of class `coxph` representing the fit. See `coxph.object` for details.

### Side Effects

Depending on the call, the `predict`, `residuals`, and `survfit` routines may need to reconstruct the `x` matrix created by `coxph`. It is possible for this to fail, as in the example below in which the `predict` function is unable to find `tform`.

```
tfun <- function(tform) coxph(tform, data=lung)
fit <- tfun(Surv(time, status) ~ age)
predict(fit)
```

In such a case add the `model=TRUE` option to the `coxph` call to obviate the need for reconstruction, at the expense of a larger fit object.

### Special terms

There are three special terms that may be used in the model equation. A `strata` term identifies a stratified Cox model; separate baseline hazard functions are fit for each strata. The `cluster` term is used to compute a robust variance for the model. The term `+ cluster(id)` where each value of `id` is unique is equivalent to specifying the `robust=T` argument. If the `id` variable is not unique, it is assumed that it identifies clusters of correlated observations. The robust estimate arises from many different arguments and thus has had many labels. It is variously known as the Huber sandwich estimator, White's estimate (linear models/econometrics), the Horvitz-Thompson estimate (survey sampling), the working independence variance (generalized estimating equations), the infinitesimal jackknife, and the Wei, Lin, Weissfeld (WLW) estimate.

A time-transform term allows variables to vary dynamically in time. In this case the `tt` argument will be a function or a list of functions (if there are more than one `tt()` term in the model) giving the appropriate transform. See the examples below.

### Convergence

In certain data cases the actual MLE estimate of a coefficient is infinity, e.g., a dichotomous variable where one of the groups has no events. When this happens the associated coefficient grows at a steady pace and a race condition will exist in the fitting routine: either the log likelihood converges, the information matrix becomes effectively singular, an argument to `exp` becomes too large for the computer hardware, or the maximum number of interactions is exceeded. (Nearly always the first occurs.) The routine attempts to detect when this has happened, not always successfully. The primary consequence for the user is that the Wald statistic = `coefficient/se(coefficient)` is not valid in this case and should be ignored; the likelihood ratio and score tests remain valid however.

### Ties

There are three possible choices for handling tied event times. The Breslow approximation is the easiest to program and hence became the first option coded for almost all computer routines. It then ended up as the default option when other options were added in order to "maintain backwards compatibility". The Efron option is more accurate if there are a large number of ties, and it is the default option here. In practice the number of ties is usually small, in which case all the methods are statistically indistinguishable.

Using the "exact partial likelihood" approach the Cox partial likelihood is equivalent to that for matched logistic regression. (The `clogit` function uses the `coxph` code to do the fit.) It is technically appropriate when the time scale is discrete and has only a few unique values, and some packages refer to this as the "discrete" option. There is also an "exact marginal likelihood" due to Prentice which is not implemented here.

The calculation of the exact partial likelihood is numerically intense. Say for instance 15 of 180 subjects at risk had an event on day 7; then the code needs to compute sums over all  $180\text{-choose-}15 > 10^{43}$  different possible subsets of size 15. There is an efficient recursive algorithm for this task, but even with this the computation can be insufferably long. With (start, stop) data it is much worse since the recursion needs to start anew for each unique start time.

### Penalized regression

coxph can now maximise a penalised partial likelihood with arbitrary user-defined penalty. Supplied penalty functions include ridge regression ([ridge](#)), smoothing splines ([pspline](#)), and frailty models ([frailty](#)).

```
# Create the simplest test data set
test1 <- list(time=c(4,3,1,1,2,2,3),
              status=c(1,1,1,0,1,1,0),
              x=c(0,2,1,1,1,0,0),
              sex=c(0,0,0,0,1,1,1))

# Fit a stratified model
coxph(Surv(time, status) ~ x + strata(sex), test1)

# Create a simple data set for a time-dependent model
test2 <- list(start=c(1,2,5,2,1,7,3,4,8,8),
              stop=c(2,3,6,7,8,9,9,9,14,17),
              event=c(1,1,1,1,1,1,1,0,0,0),
              x=c(1,0,0,1,0,1,1,1,0,0))

summary(coxph(Surv(start, stop, event) ~ x, test2))

#
# Create a simple data set for a time-dependent model
#
test2 <- list(start=c(1, 2, 5, 2, 1, 7, 3, 4, 8, 8),
              stop =c(2, 3, 6, 7, 8, 9, 9, 9,14,17),
              event=c(1, 1, 1, 1, 1, 1, 1, 0, 0, 0),
              x    =c(1, 0, 0, 1, 0, 1, 1, 1, 0, 0) )

summary( coxph( Surv(start, stop, event) ~ x, test2))

# Fit a stratified model, clustered on patients

bladder1 <- bladder[bladder$enum < 5, ]
coxph(Surv(stop, event) ~ (rx + size + number) * strata(enum) +
      cluster(id), bladder1)
```

```
# Fit a time transform model using current age
coxph(Surv(time, status) ~ ph.ecog + tt(age), data=lung,
      tt=function(x,t,...) pspline(x + t/365.25))
```

---

coxph.control

*Ancillary arguments for controlling coxph fits*

---

## Description

This is used to set various numeric parameters controlling a Cox model fit. Typically it would only be used in a call to coxph.

## Usage

```
coxph.control(eps = 1e-09, toler.chol = .Machine$double.eps^0.75,
              iter.max = 20, toler.inf = sqrt(eps), outer.max = 10, timefix=TRUE)
```

## Arguments

|            |  |
|------------|--|
| eps        | Iteration continues until the relative change in the log partial likelihood is less than eps. Must be positive.  |
| toler.chol | Tolerance for detection of singularity during a Cholesky decomposition of the variance matrix, i.e., for detecting a redundant predictor variable.                               |
| iter.max   | Maximum number of iterations to attempt for convergence.   |
| toler.inf  | Tolerance criteria for the warning message about a possible infinite coefficient value.  |
| outer.max  | For a penalized coxph model, e.g. with pspline terms, there is an outer loop of iteration to determine the penalty parameters; maximum number of iterations for this outer loop. |
| timefix    | Resolve any near ties in the time variables. (Floating point representation error can cause actual tied times to appear distinct.)   |

## Value

a list containing the values of each of the above constants

## Author(s)

Terry Therneau

[coxph](#)

coxph.detail

*Details of a Cox Model Fit***Description**

Returns the individual contributions to the first and second derivative matrix, at each unique event time.

**Usage**

```
coxph.detail(object, riskmat=FALSE)
```

**Arguments**

|         |   |
|---------|---|
| object  | a Cox model object, i.e., the result of coxph.      |
| riskmat | include the at-risk indicator matrix in the output? |

**Details**

This function may be useful for those who wish to investigate new methods or extensions to the Cox model. The example below shows one way to calculate the Schoenfeld residuals.

**Value**

a list with components

|         |   |
|---------|---|
| time    | the vector of unique event times  |
| nevent  | the number of events at each of these time points.  |
| means   | a matrix with one row for each event time and one column for each variable in the Cox model, containing the weighted mean of the variable at that time, over all subjects still at risk at that time. The weights are the risk weights $\exp(x \% \% \text{fit\$coef})$ . |
| nrisk   | number of subjects at risk.   |
| score   | the contribution to the score vector (first derivative of the log partial likelihood) at each time point.   |
| imat    | the contribution to the information matrix (second derivative of the log partial likelihood) at each time point.  |
| hazard  | the hazard increment. Note that the hazard and variance of the hazard are always for some particular future subject. This routine uses <code>object\$mean</code> as the future subject.   |
| varhaz  | the variance of the hazard increment.   |
| x,y     | copies of the input data.   |
| strata  | only present for a stratified Cox model, this is a table giving the number of time points of component time that were contributed by each of the strata.  |
| riskmat | a matrix with one row for each time and one column for each observation containing a 0/1 value to indicate whether that observation was (1) or was not (0) at risk at the given time point.   |

**See Also**

[coxph](#), [residuals.coxph](#)

**Examples**

```
fit <- coxph(Surv(futime,fustat) ~ age + rx + ecog.ps, ovarian, x=TRUE)
fitd <- coxph.detail(fit)
# There is one Schoenfeld residual for each unique death. It is a
# vector (covariates for the subject who died) - (weighted mean covariate
# vector at that time). The weighted mean is defined over the subjects
# still at risk, with exp(X beta) as the weight.

events <- fit$y[,2]==1
etime <- fit$y[events,1] #the event times --- may have duplicates
indx <- match(etime, fitd$time)
schoen <- fit$x[events,] - fitd$means[indx,]
```

---

coxph.object

*Proportional Hazards Regression Object*

---

**Description**

This class of objects is returned by the coxph class of functions to represent a fitted proportional hazards model. Objects of this class have methods for the functions print, summary, residuals, predict and survfit.

**Arguments**

|                   |  |
|-------------------|--|
| coefficients      | the vector of coefficients. If the model is over-determined there will be missing values in the vector corresponding to the redundant columns in the model matrix.                               |
| var               | the variance matrix of the coefficients. Rows and columns corresponding to any missing coefficients are set to zero.   |
| naive.var         | this component will be present only if the robust option was true. If so, the var component will contain the robust estimate of variance, and this component will contain the ordinary estimate. |
| loglik            | a vector of length 2 containing the log-likelihood with the initial values and with the final values of the coefficients.  |
| score             | value of the efficient score test, at the initial value of the coefficients.   |
| rscore            | the robust log-rank statistic, if a robust variance was requested.   |
| wald.test         | the Wald test of whether the final coefficients differ from the initial values.  |
| iter              | number of iterations used.   |
| linear.predictors | the vector of linear predictors, one per subject. Note that this vector has been centered, see predict.coxph for more details.   |
| residuals         | the martingale residuals.  |
| means             | vector of column means of the X matrix. Subsequent survival curves are adjusted to this value.   |
| n                 | the number of observations used in the fit.  |

|             |   |
|-------------|---|
| nevent      | the number of events (usually deaths) used in the fit.  |
| concordance | the concordance, as computed by survConcordance.  |
| first       | the first derivative vector at the solution.  |
| weights     | the vector of case weights, if one was used.  |
| method      | the computation method used.  |
| na.action   | the na.action attribute, if any, that was returned by the na.action routine.  |
|             | The object will also contain the following, for documentation see the lm object: terms, assign, formula, call, and, optionally, x, y, and/or frame. |

### Components

The following components must be included in a legitimate coxph object.

### See Also

[coxph](#), [coxph.detail](#), [cox.zph](#), [residuals.coxph](#), [survfit](#), [survreg](#).

---

|             |                                 |
|-------------|---------------------------------|
| coxph.wtest | <i>Compute a quadratic form</i> |
|-------------|---------------------------------|

---

### Description

This function is used internally by several survival routines. It computes a simple quadratic form, while properly dealing with missings.

### Usage

```
coxph.wtest(var, b, toler.chol = 1e-09)
```

### Arguments

|            |   |
|------------|---|
| var        | variance matrix                                   |
| b          | vector  |
| toler.chol | tolerance for the internal cholesky decomposition |

### Details

Compute  $b' V^{-1} b$ . Equivalent to `sum(b * solve(V,b))`, except for the case of redundant covariates in the original model, which lead to NA values in V and b.

### Value

a real number

### Author(s)

Terry Therneau

dsurvreg

*Distributions available in survreg.***Description**

Density, cumulative distribution function, quantile function and random generation for the set of distributions supported by the survreg function.

**Usage**

```
dsurvreg(x, mean, scale=1, distribution='weibull', parms)
psurvreg(q, mean, scale=1, distribution='weibull', parms)
qsurvreg(p, mean, scale=1, distribution='weibull', parms)
rsurvreg(n, mean, scale=1, distribution='weibull', parms)
```

**Arguments**

|              |   |
|--------------|---|
| x            | vector of quantiles. Missing values (NAs) are allowed.  |
| q            | vector of quantiles. Missing values (NAs) are allowed.  |
| p            | vector of probabilities. Missing values (NAs) are allowed.  |
| n            | number of random deviates to produce  |
| mean         | vector of linear predictors for the model. This is replicated to be the same length as p, q or n.               |
| scale        | vector of (positive) scale factors. This is replicated to be the same length as p, q or n.                      |
| distribution | character string giving the name of the distribution. This must be one of the elements of survreg.distributions |
| parms        | optional parameters, if any, of the distribution. For the t-distribution this is the degrees of freedom.        |

**Details**

Elements of q or p that are missing will cause the corresponding elements of the result to be missing.

The location and scale values are as they would be for survreg. The label "mean" was an unfortunate choice (made in mimicry of qnorm); since almost none of these distributions are symmetric it will not actually be a mean, but corresponds instead to the linear predictor of a fitted model. Translation to the usual parameterization found in a textbook is not always obvious. For example, the Weibull distribution is fit using the Extreme value distribution along with a log transformation. Letting  $F(t) = 1 - \exp[-(at)^p]$  be the cumulative distribution of the Weibull using a standard parameterization in terms of  $a$  and  $p$ , the survreg location corresponds to  $-\log(a)$  and the scale to  $1/p$  (Kalbfleisch and Prentice, section 2.2.2).

**Value**

density (dsurvreg), probability (psurvreg), quantile (qsurvreg), or for the requested distribution with mean and scale parameters mean and sd.

haz <- dsurvreg(x, 2, 3)/ (1-psurvreg(x, 2, 3))
## Not run:
plot(x, haz, log='xy', ylab="Hazard") #line with slope (1/scale -1)

## End(Not run)
```

---

`finegray`

*Create data for a Fine-Gray model*

---

## Description

The Fine-Gray model can be fit by first creating a special data set, and then fitting a weighted Cox model to the result. This routine creates the data set.

## Usage

```
finegray(formula, data, subset, na.action= na.pass, etype,
         prefix="fg", count, id, timefix=TRUE)
```

## Arguments

|                        |  |
|------------------------|--|
| <code>formula</code>   | a standard model formula, with survival on the left and covariates on the right.   |
| <code>data</code>      | an optional data frame, list or environment (or object coercible by <code>as.data.frame</code> to a data frame) containing the variables in the model. |
| <code>subset</code>    | an optional vector specifying a subset of observations to be used in the fitting process.  |
| <code>na.action</code> | a function which indicates what should happen when the data contain NAs. The default is set by the <code>na.action</code> setting of options.          |

|                      |  |
|----------------------|--|
| <code>etype</code>   | the event type for which a data set will be generated. The default is to use whichever is listed first in the multi-state survival object.   |
| <code>prefix</code>  | the routine will add 4 variables to the data set: a start and end time for each interval, status, and a weight for the interval. The default names of these are "fgstart", "fgstop", "fgstatus", and "fgwt"; the <code>prefix</code> argument determines the initial portion of the new names. |
| <code>count</code>   | a variable name in the output data set for an optional variable that will contain the the replication count for each row of the input data. If a row is expanded into multiple lines it will contain 1, 2, etc.  |
| <code>id</code>      | optional, the variable name in the data set which identifies subjects.   |
| <code>timefix</code> | process times through the <code>aeqSurv</code> function to eliminate potential roundoff issues.  |

## Details

The function expects a multi-state survival expression or variable as the left hand side of the formula, e.g. `Surv(atime, astat)` where `astat` is a factor whose first level represents censoring and remaining levels are states. The output data set will contain simple survival data (`status = 0` or `1`) for a single endpoint of interest. In the output data set subjects who did not experience the event of interest become censored subjects whose times are artificially extended over multiple intervals, with a decreasing case weight from interval to interval. The output data set will normally contain many more rows than the input.

Time dependent covariates are allowed, but not (currently) delayed entry. If there are time dependent covariates, e.g., the input data set had `Surv(entry, exit, stat)` as the left hand side, then an `id` statement is required. The program does data checks in this case, and needs to know which rows belong to each subject.

See the competing risks vignette for more details.

## Value

a data frame

# Treat time to death and plasma cell malignancy as competing risks
etime <- with(mgus2, ifelse(pstat==0, futime, ptime))
event <- with(mgus2, ifelse(pstat==0, 2*death, 1))
event <- factor(event, 0:2, labels=c("censor", "pcm", "death"))

# FG model for PCM
pdata <- finegray(Surv(etime, event) ~ ., data=mgus2)
fgfit <- coxph(Surv(fgstart, fgstop, fgstatus) ~ age + sex,
               weight=fgwt, data=pdata)

# Compute the weights separately by sex
adata <- finegray(Surv(etime, event) ~ . + strata(sex),
                  data=mgus2, na.action=na.pass)
```

flchain

*Assay of serum free light chain for 7874 subjects.***Description**

This is a stratified random sample containing 1/2 of the subjects from a study of the relationship between serum free light chain (FLC) and mortality. The original sample contains samples on approximately 2/3 of the residents of Olmsted County aged 50 or greater.

**Usage**

```
data(flchain)
```

**Format**

A data frame with 7874 persons containing the following variables.

age age in years

sex F=female, M=male

sample.yr the calendar year in which a blood sample was obtained

kappa serum free light chain, kappa portion

lambda serum free light chain, lambda portion

flc.grp the FLC group for the subject, as used in the original analysis

creatinine serum creatinine

mgus 1 if the subject had been diagnosed with monoclonal gammopathy (MGUS)

futime days from enrollment until death. Note that there are 3 subjects whose sample was obtained on their death date.

death 0=alive at last contact date, 1=dead

chapter for those who died, a grouping of their primary cause of death by chapter headings of the International Code of Diseases ICD-9

## Details

In 1995 Dr. Robert Kyle embarked on a study to determine the prevalence of monoclonal gammopathy of undetermined significance (MGUS) in Olmsted County, Minnesota, a condition which is normally only found by chance from a test (serum electrophoresis) which is ordered for other causes. Later work suggested that one component of immunoglobulin production, the serum free light chain, might be a possible marker for immune dysregulation. In 2010 Dr. Angela Dispenzieri and colleagues assayed FLC levels on those samples from the original study for which they had patient permission and from which sufficient material remained for further testing. They found that elevated FLC levels were indeed associated with higher death rates.

Patients were recruited when they came to the clinic for other appointments, with a final random sample of those who had not yet had a visit since the study began. An interesting side question is whether there are differences between early, mid, and late recruits.

This data set contains an age and sex stratified random sample that includes 7874 of the original 15759 subjects. The original subject identifiers and dates have been removed to protect patient identity. Subsampling was done to further protect this information.

table(flchain$sex, age.grp)
```

---

frailty

*Random effects terms*

---

## Description

The frailty function allows one to add a simple random effects term to a Cox or survreg model.

## Usage

```
frailty(x, distribution="gamma", ...)
frailty.gamma(x, sparse = (nclass > 5), theta, df, eps = 1e-05,
             method = c("em", "aic", "df", "fixed"), ...)
frailty.gaussian(x, sparse = (nclass > 5), theta, df,
```

```

method = c("reml", "aic", "df", "fixed"), ...)
frailty.t(x, sparse = (nclass > 5), theta, df, eps = 1e-05, tdf = 5,
method = c("aic", "df", "fixed"), ...)

```

### Arguments

|                           |  |
|---------------------------|--|
| <code>x</code>            | the variable to be entered as a random effect. It is always treated as a factor.   |
| <code>distribution</code> | either the gamma, gaussian or t distribution may be specified. The routines <code>frailty.gamma</code> , <code>frailty.gaussian</code> and <code>frailty.t</code> do the actual work.  |
| <code>...</code>          | Arguments for specific distribution, including (but not limited to)  |
| <code>sparse</code>       | cutoff for using a sparse coding of the data matrix. If the total number of levels of <code>x</code> is larger than this value, then a sparse matrix approximation is used. The correct cutoff is still a matter of exploration: if the number of levels is very large (thousands) then the non-sparse calculation may not be feasible in terms of both memory and compute time. Likewise, the accuracy of the sparse approximation appears to be related to the maximum proportion of subjects in any one class, being best when no one class has a large membership.   |
| <code>theta</code>        | if specified, this fixes the variance of the random effect. If not, the variance is a parameter, and a best solution is sought. Specifying this implies <code>method='fixed'</code> .  |
| <code>df</code>           | if specified, this fixes the degrees of freedom for the random effect. Specifying this implies <code>method='df'</code> . Only one of <code>theta</code> or <code>df</code> should be specified.   |
| <code>method</code>       | the method used to select a solution for <code>theta</code> , the variance of the random effect. The <code>fixed</code> corresponds to a user-specified value, and no iteration is done. The <code>df</code> selects the variance such that the degrees of freedom for the random effect matches a user specified value. The <code>aic</code> method seeks to maximize Akaike's information criteria $2 \times (\text{partial likelihood} - df)$ . The <code>em</code> and <code>reml</code> methods are specific to Cox models with gamma and gaussian random effects, respectively. Please see further discussion below. |
| <code>tdf</code>          | the degrees of freedom for the t-distribution.   |
| <code>eps</code>          | convergence criteria for the iteration on <code>theta</code> .   |

### Details

The frailty plugs into the general penalized modeling framework provided by the `coxph` and `survreg` routines. This framework deals with likelihood, penalties, and degrees of freedom; these aspects work well with either parent routine.

Therneau, Grambsch, and Pankratz show how maximum likelihood estimation for the Cox model with a gamma frailty can be accomplished using a general penalized routine, and Ripatti and Palmgren work through a similar argument for the Cox model with a gaussian frailty. Both of these are specific to the Cox model. Use of `gamma/ml` or `gaussian/reml` with `survreg` does not lead to valid results.

The extensible structure of the penalized methods is such that the penalty function, such as `frailty` or `pspine`, is completely separate from the modeling routine. The strength of this is that a user can plug in any penalization routine they choose. A weakness is that it is very difficult for the modeling routine to know whether a sensible penalty routine has been supplied.

Note that use of a frailty term implies a mixed effects model and use of a cluster term implies a GEE approach; these cannot be mixed.

The `coxme` package has superseded this method. It is faster, more stable, and more flexible.

**Value**

this function is used in the model statement of either `coxph` or `survreg`. It's results are used internally.

  frailty.gaussian(litter, df=13, sparse=TRUE), rats,
  subset= (sex=='f'))
```

---

genfan

*Generator fans*

---

**Description**

The data come from a field engineering study of the time to failure of diesel generator fans. The ultimate goal was to decide whether or not to replace the working fans with a higher quality fan to prevent future failures. Seventy generators were studied. For each one, the number of hours of running time from its first being put into service until fan failure or until the end of the study (whichever came first) was recorded.

**Usage**

```
data("genfan")
```

**Format**

A data frame with 70 observations on the following 2 variables.

hours hours of service

status 1=failure, 0=censored

---

|              |   |
|--------------|---|
| is.ratetable | <i>Verify that an object is of class ratetable.</i> |
|--------------|---|

---

**Description**

The function verifies not only the class attribute, but the structure of the object.

**Usage**

```
is.ratetable(x, verbose=FALSE)
```

**Arguments**

- x                    the object to be verified.
- verbose            if TRUE and the object is not a ratetable, then return a character string describing the way(s) in which x fails to be a proper ratetable object.

**Details**

Rate tables are used by the pyears and survexp functions, and normally contain death rates for some population, categorized by age, sex, or other variables. They have a fairly rigid structure, and the verbose option can help in creating a new rate table.

**Value**

returns TRUE if x is a ratetable, and FALSE or a description if it is not.

**See Also**

**Examples**

```
is.ratetable(survexp.us) # True
is.ratetable(cancer)    # False
```

---

|        |                             |
|--------|-----------------------------|
| kidney | <i>Kidney catheter data</i> |
|--------|-----------------------------|

---

**Description**

Data on the recurrence times to infection, at the point of insertion of the catheter, for kidney patients using portable dialysis equipment. Catheters may be removed for reasons other than infection, in which case the observation is censored. Each patient has exactly 2 observations.

This data has often been used to illustrate the use of random effects (frailty) in a survival model. However, one of the males (id 21) is a large outlier, with much longer survival than his peers. If this observation is removed no evidence remains for a random subject effect.

**Format**

```

patient:  id
time:     time
status:   event status
age:      in years
sex:      1=male, 2=female
disease:  disease type (0=GN, 1=AN, 2=PKD, 3=Other)
frail:    frailty estimate from original paper

```

### Note

The original paper ignored the issue of tied times and so is not exactly reproduced by the survival package.

### Source

CA McGilchrist, CW Aisbett (1991), Regression with frailty in survival analysis. *Biometrics* **47**, 461–66.

### Examples

```

kfit <- coxph(Surv(time, status)~ age + sex + disease + frailty(id), kidney)
kfit0 <- coxph(Surv(time, status)~ age + sex + disease, kidney)
kfitm1 <- coxph(Surv(time,status) ~ age + sex + disease +
  frailty(id, dist='gauss'), kidney)

```

---

lines.survfit

*Add Lines or Points to a Survival Plot*

---

### Description

Often used to add the expected survival curve(s) to a Kaplan-Meier plot generated with plot.survfit.

### Usage

```

## S3 method for class 'survfit'
lines(x, type="s", mark=3, col=1, lty=1,
      lwd=1, cex=1, mark.time=FALSE,
      xscale=1, firstx=0, firsty=1, xmax, fun, conf.int=FALSE,
      conf.times, conf.cap=.005, conf.offset=.012, ...)
## S3 method for class 'survexp'
lines(x, type="l", ...)
## S3 method for class 'survfit'
points(x, xscale, xmax, fun, censor=FALSE, col=1, pch,
      ...)

```

**Arguments**

|                                       |  |
|---------------------------------------|--|
| <code>x</code>                        | a survival object, generated from the <code>survfit</code> or <code>survexp</code> functions.  |
| <code>type</code>                     | the line type, as described in <code>lines</code> . The default is a step function for <code>survfit</code> objects, and a connected line for <code>survexp</code> objects. All other arguments for <code>lines.survexp</code> are identical to those for <code>lines.survfit</code> .   |
| <code>mark, col, lty, lwd, cex</code> | vectors giving the mark symbol, color, line type, line width and character size for the added curves. Of this set only color is applicable to points.  |
| <code>pch</code>                      | plotting characters for points, in the style of <code>matplot</code> , i.e., either a single string of characters of which the first will be used for the first curve, etc; or a vector of characters or integers, one element per curve.  |
| <code>censor</code>                   | should censoring times be displayed for the points function?   |
| <code>...</code>                      | other graphical parameters   |
| <code>mark.time</code>                | controls the labeling of the curves. If <code>FALSE</code> , no labeling is done. If <code>TRUE</code> , then curves are marked at each censoring time. If <code>mark.time</code> is a numeric vector, then curves are marked at the specified time points.  |
| <code>xscale</code>                   | this parameter is no longer necessary and is ignored. See the note in <a href="#">plot.survfit</a> .   |
| <code>firstx, firsty</code>           | the starting point for the survival curves. If either of these is set to <code>NA</code> or <code>&lt; blank</code> > the plot will start at the first time point of the curve.  |
| <code>xmax</code>                     | the maximum horizontal plot coordinate. This shortens the curve before plotting it, so unlike using the <code>xlim</code> graphical parameter, warning messages about out of bounds points are not generated.  |
| <code>fun</code>                      | an arbitrary function defining a transformation of the survival curve. For example <code>fun=log</code> is an alternative way to draw a log-survival curve (but with the axis labeled with $\log(S)$ values). Four often used transformations can be specified with a character argument instead: "log" is the same as using the <code>log=T</code> option, "event" plots cumulative events ( $f(y) = 1-y$ ), "cumhaz" plots the cumulative hazard function ( $f(y) = -\log(y)$ ) and "cloglog" creates a complimentary log-log survival plot ( $f(y) = \log(-\log(y))$ ) along with log scale for the x-axis. |
| <code>conf.int</code>                 | if <code>TRUE</code> , confidence bands for the curves are also plotted. If set to "only", then only the CI bands are plotted, and the curve itself is left off. This can be useful for fine control over the colors or line types of a plot.  |
| <code>conf.times</code>               | optional vector of times at which to place a confidence bar on the curve(s). If present, these will be used instead of confidence bands.   |
| <code>conf.cap</code>                 | width of the horizontal cap on top of the confidence bars; only used if <code>conf.times</code> is used. A value of 1 is the width of the plot region.   |
| <code>conf.offset</code>              | the offset for confidence bars, when there are multiple curves on the plot. A value of 1 is the width of the plot region. If this is a single number then each curve's bars are offset by this amount from the prior curve's bars, if it is a vector the values are used directly.   |

**Details**

When the `survfit` function creates a multi-state survival curve the resulting object has class 'survfitms'. The only difference in the plots is that that it defaults to a curve that goes from lower left to upper right (starting at 0), where survival curves default to starting at 1 and going down. All other options are identical.

**Value**

a list with components `x` and `y`, containing the coordinates of the last point on each of the curves (but not of the confidence limits). This may be useful for labeling.

**Side Effects**

one or more curves are added to the current plot.

**See Also**

**Examples**

```
fit <- survfit(Surv(time, status==2) ~ sex, pbc, subset=1:312)
plot(fit, mark.time=FALSE, xscale=365.25,
     xlab='Years', ylab='Survival')
lines(fit[1], lwd=2)      #darken the first curve and add marks

# Add expected survival curves for the two groups,
# based on the US census data
# The data set does not have entry date, use the midpoint of the study
efit <- survexp(~ ratetable(sex=sex, age=age*365.35, year=as.Date('1979/1/1')) +
               sex, data=dbc, times=(0:24)*182)
temp <- lines(efit, lty=2, lwd=2:1)
text(temp, c("Male", "Female"), adj= -.1) #labels just past the ends
title(main="Primary Biliary Cirrhosis, Observed and Expected")
```

---

logan

*Data from the 1972-78 GSS data used by Logan*

---

**Description**

Intergenerational occupational mobility data with covariates.

**Usage**

```
data(logan)
```

**Format**

A data frame with 838 observations on the following 4 variables.

**occupation** subject's occupation, a factor with levels farm, operatives, craftsmen, sales, and professional

**focc** father's occupation

**education** total years of schooling, 0 to 20

**race** levels of non-black and black

**Source**

|--------------|--------------------------------------|
| logLik.coxph | <i>logLik method for a Cox model</i> |
|--------------|--------------------------------------|

---

**Description**

The logLik function for survival models

**Usage**

```
## S3 method for class 'coxph'
logLik(object, ...)
## S3 method for class 'survreg'
logLik(object, ...)
```

**Arguments**

|        |  |
|--------|--|
| object | the result of a coxph or survreg fit                 |
| ...    | optional arguments for other instances of the method |

**Details**

The logLik function is used by summary functions in R such as AIC. For a Cox model, this method returns the partial likelihood. The number of degrees of freedom (df) used by the fit and the effective number of observations (nobs) are added as attributes. Per Raftery and others, the effective number of observations is the taken to be the number of events in the data set.

For a survreg model the proper value for the effective number of observations is still an open question (at least to this author). For right censored data the approach of logLik.coxph is the possible the most sensible, but for interval censored observations the result is unclear. The code currently does not add a *nobs* attribute.

**Value**

an object of class logLik

**Author(s)**

Terry Therneau

mgus

*Monoclonal gammopathy data***Description**

Natural history of 241 subjects with monoclonal gammopathy of undetermined significance (MGUS).

**Usage**

mgus  
mgus1

**Format**

mgus: A data frame with 241 observations on the following 12 variables.

id: subject id  
 age: age in years at the detection of MGUS  
 sex: male or female  
 dxyr: year of diagnosis  
 pcdx: for subjects who progress to a plasma cell malignancy  
       the subtype of malignancy: multiple myeloma (MM) is the  
       most common, followed by amyloidosis (AM), macroglobulinemia (MA),  
       and other lymphoproliferative disorders (LP)  
 pctime: days from MGUS until diagnosis of a plasma cell malignancy  
 futime: days from diagnosis to last follow-up  
 death: 1= follow-up is until death  
 alb: albumin level at MGUS diagnosis  
 creat: creatinine at MGUS diagnosis  
 hgb: hemoglobin at MGUS diagnosis  
 mspike: size of the monoclonal protein spike at diagnosis

mgus1: The same data set in start,stop format. Contains the id, age, sex, and laboratory variable described above along with

start, stop: sequential intervals of time for each subject  
 status: =1 if the interval ends in an event  
 event: a factor containing the event type: censor, death, or plasma cell malignancy  
 enum: event number for each subject: 1 or 2

**Details**

Plasma cells are responsible for manufacturing immunoglobulins, an important part of the immune defense. At any given time there are estimated to be about  $10^6$  different immunoglobulins in the circulation at any one time. When a patient has a plasma cell malignancy the distribution will become dominated by a single isotype, the product of the malignant clone, visible as a spike on a serum protein electrophoresis. Monoclonal gammopathy of undertermined significance (MGUS) is the presence of such a spike, but in a patient with no evidence of overt malignancy. This data set of 241 sequential subjects at Mayo Clinic was the groundbreaking study defining the natural

history of such subjects. Due to the diligence of the principle investigator 0 subjects have been lost to follow-up.

Three subjects had MGUS detected on the day of death. In data set mgus1 these subjects have the time to MGUS coded as .5 day before the death in order to avoid tied times.

These data sets were updated in Jan 2015 to correct some small errors.

### Source

Mayo Clinic data courtesy of Dr. Robert Kyle.

### References

R Kyle, Benign monoclonal gammopathy – after 20 to 35 years of follow-up, Mayo Clinic Proc 1993; 68:26-36.

### Examples

```
# Create the competing risk curves for time to first of death or PCM
sfit <- survfit(Surv(start, stop, event) ~ sex, mgus1, subset=(enum==1))
print(sfit) # the order of printout is the order in which they plot

plot(sfit, xscale=365.25, lty=c(2,1,2,1), col=c(1,1,2,2),
      xlab="Years after MGUS detection", ylab="Proportion")
legend(0, .8, c("Death/male", "Death/female", "PCM/male", "PCM/female"),
      lty=c(1,1,2,2), col=c(2,1,2,1), bty='n')

title("Curves for the first of plasma cell malignancy or death")
# The plot shows that males have a higher death rate than females (no
# surprise) but their rates of conversion to PCM are essentially the same.
```

---

mgus2

*Monoclonal gammopathy data*

---

### Description

Natural history of 1341 sequential patients with monoclonal gammopathy of undetermined significance (MGUS).

### Usage

```
data("mgus2")
```

### Format

A data frame with 1384 observations on the following 10 variables.

id subject identifier

age age at diagnosis, in years

sex a factor with levels F M

hgb hemoglobin

creat creatinine

mspike size of the monoclonal serum spike  
 ptime time until progression to a plasma cell malignancy (PCM) or last contact, in months  
 pstat occurrence of PCM: 0=no, 1=yes  
 futime time until death or last contact, in months  
 death occurrence of death: 0=no, 1=yes

### Details

This is a larger follow-on study of the condition also found in data set mgus.

### Source

Mayo Clinic data courtesy of Dr. Robert Kyle. All patient identifiers have been removed, age rounded to the nearest year, and follow-up times rounded to the nearest month.

### References

---

|                   |   |
|-------------------|---|
| model.frame.coxph | <i>Model.frame method for coxph objects</i> |
|-------------------|---|

---

### Description

Recreate the model frame of a coxph fit.

### Usage

```
## S3 method for class 'coxph'
model.frame(formula, ...)
```

### Arguments

|         |                                |
|---------|--------------------------------|
| formula | the result of a coxph fit      |
| ...     | other arguments to model.frame |

### Details

For details, see the manual page for the generic function. This function would rarely be called by a user, it is mostly used inside functions like `residual` that need to recreate the data set from a model in order to do further calculations.

### Value

the model frame used in the original fit, or a parallel one for new data.

### Author(s)

Terry Therneau

**See Also**[model.frame](#)

---

|                    |   |
|--------------------|---|
| model.matrix.coxph | <i>Model.matrix method for coxph models</i> |
|--------------------|---|

---

**Description**

Reconstruct the model matrix for a cox model.

**Usage**

```
## S3 method for class 'coxph'
model.matrix(object, data=NULL, contrast.arg =
  object$contrasts, ...)
```

**Arguments**

|              |   |
|--------------|---|
| object       | the result of a coxph model   |
| data         | optional, a data frame from which to obtain the data                |
| contrast.arg | optional, a contrasts object describing how factors should be coded |
| ...          | other possible argument to model.frame                              |

**Details**

When there is a data argument this function differs from most of the other model.matrix methods in that the response variable for the original formula is *not* required to be in the data.

If the data frame contains a terms attribute then it is assumed to be the result of a call to model.frame, otherwise a call to model.frame is applied with the data as an argument.

**Value**

The model matrix for the fit

**Author(s)**

Terry Therneau

**See Also**[model.matrix](#)**Examples**

```
fit1 <- coxph(Surv(time, status) ~ age + factor(ph.ecog), data=lung)
xfit <- model.matrix(fit1)

fit2 <- coxph(Surv(time, status) ~ age + factor(ph.ecog), data=lung,
              x=TRUE)
all.equal(model.matrix(fit1), fit2$x)
```

---

|         |                               |
|---------|-------------------------------|
| myeloid | <i>Acute myeloid leukemia</i> |
|---------|-------------------------------|

---

### Description

This simulated data set is based on a trial in acute myeloid leukemia.

### Format

A data frame with 646 observations on the following 9 variables.

id subject identifier, 1-646  
 trt treatment arm A or B  
 futime time to death or last follow-up  
 death 1 if futime is a death, 0 for censoring  
 txtime time to hematropetic stem cell transplant  
 crtime time to complete response  
 rltime time to relapse of disease

### Details

This data set is used to illustrate multi-state survival curves. The correlation between within-subject event times strongly resembles that from an actual trial, but none of the actual data values are from that source.

### Examples

```
coxph(Surv(futime, death) ~ trt, data=myeloid)
# See the mstate vignette for a more complete analysis
```

---

|          |   |
|----------|---|
| neardate | <i>Find the index of the closest value in data set 2, for each entry in data set one.</i> |
|----------|---|

---

### Description

A common task in medical work is to find the closest lab value to some index date, for each subject.

### Usage

```
neardate(id1, id2, y1, y2, best = c("after", "prior"),
  nomatch = NA_integer_)
```

```

#first cholesterol on or after enrollment
indx1 <- neardate(data1$id, data2$id, data1$entry.dt, data2$lab.dt)
data2[indx1, "chol"]

# Closest one, either before or after.
#
indx2 <- neardate(data1$id, data2$id, data1$entry.dt, data2$lab.dt,
                  best="prior")
ifelse(is.na(indx1), indx2, # none after, take before
       ifelse(is.na(indx2), indx1, #none before
              ifelse(abs(data2$lab.dt[indx2]- data1$entry.dt) <
                     abs(data2$lab.dt[indx1]- data1$entry.dt), indx2, indx1)))

# closest date before or after, but no more than 21 days prior to index
indx2 <- ifelse((data1$entry.dt - data2$lab.dt[indx2]) >21, NA, indx2)
ifelse(is.na(indx1), indx2, # none after, take before
       ifelse(is.na(indx2), indx1, #none before
              ifelse(abs(data2$lab.dt[indx2]- data1$entry.dt) <
                     abs(data2$lab.dt[indx1]- data1$entry.dt), indx2, indx1)))

```

nwtco

pbc

*Mayo Clinic Primary Biliary Cirrhosis Data***Description**

D This data is from the Mayo Clinic trial in primary biliary cirrhosis (PBC) of the liver conducted between 1974 and 1984. A total of 424 PBC patients, referred to Mayo Clinic during that ten-year interval, met eligibility criteria for the randomized placebo controlled trial of the drug D-penicillamine. The first 312 cases in the data set participated in the randomized trial and contain

largely complete data. The additional 112 cases did not participate in the clinical trial, but consented to have basic measurements recorded and to be followed for survival. Six of those cases were lost to follow-up shortly after diagnosis, so the data here are on an additional 106 cases as well as the 312 randomized participants.

A nearly identical data set found in appendix D of Fleming and Harrington; this version has fewer missing values.

## Source

T Therneau and P Grambsch (2000), *Modeling Survival Data: Extending the Cox Model*, Springer-Verlag, New York. ISBN: 0-387-98784-3.

## Description

This data is a continuation of the PBC data set, and contains the follow-up laboratory data for each study patient. An analysis based on the data can be found in Murtagh, et. al.

The primary PBC data set contains only baseline measurements of the laboratory parameters. This data set contains multiple laboratory results, but only on the 312 randomized patients. Some baseline data values in this file differ from the original PBC file, for instance, the data errors in prothrombin time and age which were discovered after the original analysis (see Fleming and Harrington, figure 4.6.7).

One "feature" of the data deserves special comment. The last observation before death or liver transplant often has many more missing covariates than other data rows. The original clinical protocol for these patients specified visits at 6 months, 1 year, and annually thereafter. At these protocol visits lab values were obtained for a large pre-specified battery of tests. "Extra" visits, often undertaken because of worsening medical condition, did not necessarily have all this lab work. The missing values are thus potentially informative.

plot.aareg

---

*Plot an aareg object.*

---

**Description**

Plot the estimated coefficient function(s) from a fit of Aalen's additive regression model.

**Usage**

```
## S3 method for class 'aareg'
plot(x, se=TRUE, maxtime, type='s', ...)
```

**Arguments**

|         |  |
|---------|--|
| x       | the result of a call to the aareg function                           |
| se      | if TRUE, standard error bands are included on the plot               |
| maxtime | upper limit for the x-axis.  |
| type    | graphical parameter for the type of line, default is "steps".        |
| ...     | other graphical parameters such as line type, color, or axis labels. |

**Side Effects**

A plot is produced on the current graphical device.

**References**

Aalen, O.O. (1989). A linear regression model for the analysis of life times. Statistics in Medicine, 8:907-925.

aareg

---

|              |   |
|--------------|---|
| plot.cox.zph | <i>Graphical Test of Proportional Hazards</i> |
|--------------|---|

---

Description

Displays a graph of the scaled Schoenfeld residuals, along with a smooth curve.

Usage

```
## S3 method for class 'cox.zph'
plot(x, resid=TRUE, se=TRUE, df=4, nsmo=40, var,
      xlab="Time", ylab, lty=1:2, col=1, lwd=1, ...)
```

Arguments

|               |   |
|---------------|---|
| x             | result of the cox.zph function.   |
| resid         | a logical value, if TRUE the residuals are included on the plot, as well as the smooth fit.   |
| se            | a logical value, if TRUE, confidence bands at two standard errors will be added.  |
| df            | the degrees of freedom for the fitted natural spline, df=2 leads to a linear fit.   |
| nsmo          | number of points to use for the lines   |
| var           | the set of variables for which plots are desired. By default, plots are produced in turn for each variable of a model. Selection of a single variable allows other features to be added to the plot, e.g., a horizontal line at zero or a main title. This has been superseded by a subscripting method; see the example below. |
| xlab          | label for the x-axis of the plot  |
| ylab          | optional label for the y-axis of the plot. If missing a default label is provided. This can be a vector of labels.  |
| lty, col, lwd | line type, color, and line width for the overlaid curve. Each of these can be vector of length 2, in which case the second element is used for the confidence interval.   |
| ...           | additional graphical arguments passed to the plot function.   |

Side Effects

a plot is produced on the current graphics device.

See Also

[coxph](#), [cox.zph](#).

**Examples**

```
vfit <- coxph(Surv(time,status) ~ trt + factor(celltype) +
              karno + age, data=veteran, x=TRUE)

plot(temp, var=5)      # Look at Karnofsky score, old way of doing plot
plot(temp$y)           # New way with subscripting
abline(0, 0, lty=3)
# Add the linear fit as well
abline(lm(temp$y[,5] ~ temp$x)$coefficients, lty=4, col=3)
title(main="VA Lung Study")
```

plot.survfit

*Plot method for survfit objects***Description**

A plot of survival curves is produced, one curve for each strata. The `log=T` option does extra work to avoid `log(0)`, and to try to create a pleasing result. If there are zeros, they are plotted by default at 0.8 times the smallest non-zero value on the curve(s).

Curves are plotted in the same order as they are listed by `print` (which gives a 1 line summary of each). This will be the order in which `col`, `lty`, etc are used.

**Usage**

```
## S3 method for class 'survfit'
plot(x, conf.int=, mark.time=FALSE,
     mark=3, col=1, lty=1, lwd=1, cex=1, log=FALSE, xscale=1, yscale=1,
     firstx=0, firsty=1, xmax, ymin=0, fun,
     xlab="", ylab="", xaxs="S", conf.times, conf.cap=.005,
     conf.offset=.012, ...)
```

**Arguments**

|                        |   |
|------------------------|---|
| <code>x</code>         | an object of class <code>survfit</code> , usually returned by the <code>survfit</code> function.  |
| <code>conf.int</code>  | determines whether confidence intervals will be plotted. The default is to do so if there is only 1 curve, i.e., no strata.   |
| <code>mark.time</code> | controls the labeling of the curves. If set to <code>FALSE</code> , no labeling is done. If <code>TRUE</code> , then curves are marked at each censoring time which is not also a death time. If <code>mark.time</code> is a numeric vector, then curves are marked at the specified time points. |
| <code>mark</code>      | vector of mark parameters, which will be used to label the curves. The lines help file contains examples of the possible marks. The vector is reused cyclically if it is shorter than the number of curves. If it is present this implies <code>mark.time = TRUE</code> .                         |
| <code>col</code>       | a vector of integers specifying colors for each curve. The default value is 1.  |
| <code>lty</code>       | a vector of integers specifying line types for each curve. The default value is 1.  |
| <code>lwd</code>       | a vector of numeric values for line widths. The default value is 1.   |
| <code>cex</code>       | a numeric value specifying the size of the marks. This is not treated as a vector; all marks have the same size.  |

|                |   |
|----------------|---|
| log            | a logical value, if TRUE the y axis will be on a log scale. Alternately, one of the standard character strings "x", "y", or "xy" can be given to specific logarithmic horizontal and/or vertical axes.  |
| yscale         | a numeric value used to multiply the labels on the y axis. A value of 100, for instance, would be used to give a percent scale. Only the labels are changed, not the actual plot coordinates, so that adding a curve with "lines(surv.exp(...))", say, will perform as it did without the yscale argument.  |
| xscale         | a numeric value used like yscale for labels on the x axis. A value of 365.25 will give labels in years instead of the original days.  |
| firstx, firsty | the starting point for the survival curves. If either of these is set to NA the plot will start at the first time point of the curve. By default, the plot program obeys tradition by having the plot start at (0,0).<br>If start.time argument is used in survfit, firstx is set to that value.  |
| xmax           | the maximum horizontal plot coordinate. This can be used to shrink the range of a plot. It shortens the curve before plotting it, so that unlike using the xlim graphical parameter, warning messages about out of bounds points are not generated.   |
| ymin           | lower boundary for y values. Survival curves are most often drawn in the range of 0-1, even if none of the curves approach zero. The parameter is ignored if the fun argument is present, or if it has been set to NA.  |
| fun            | an arbitrary function defining a transformation of the survival curve. For example fun=log is an alternative way to draw a log-survival curve (but with the axis labeled with log(S) values), and fun=sqrt would generate a curve on square root scale. Four often used transformations can be specified with a character argument instead: "log" is the same as using the log=T option, "event" plots cumulative events ( $f(y) = 1 - y$ ), "cumhaz" plots the cumulative hazard function ( $f(y) = -\log(y)$ ), and "cloglog" creates a complimentary log-log survival plot ( $f(y) = \log(-\log(y))$ ) along with log scale for the x-axis). |
| xlab           | label given to the x-axis.  |
| ylab           | label given to the y-axis.  |
| xaxs           | either "S" for a survival curve or a standard x axis style as listed in par. Survival curves are usually displayed with the curve touching the y-axis, but not touching the bounding box of the plot on the other 3 sides. Type "S" accomplishes this by manipulating the plot range and then using the "i" style internally.   |
| conf.times     | optional vector of times at which to place a confidence bar on the curve(s). If present, these will be used instead of confidence bands.  |
| conf.cap       | width of the horizontal cap on top of the confidence bars; only used if conf.times is used. A value of 1 is the width of the plot region.   |
| conf.offset    | the offset for confidence bars, when there are multiple curves on the plot. A value of 1 is the width of the plot region. If this is a single number then each curve's bars are offset by this amount from the prior curve's bars, if it is a vector the values are used directly.  |
| ...            | for future methods  |

## Details

When the survfit function creates a multi-state survival curve the resulting object also has class 'survfitms'. Competing risk curves are a common case. The only difference in the plots is that

multi-state defaults to a curve that goes from lower left to upper right (starting at 0), where survival curves by default start at 1 and go down. All other options are identical.

When the `conf.times` argument is used, the confidence bars are offset by `conf.offset` units to avoid overlap. The bar on each curve are the confidence interval for the time point at which the bar is drawn, i.e., different time points for each curve. If curves are steep at that point, the visual impact can sometimes substantially differ for positive and negative values of `conf.offset`.

### Value

a list with components `x` and `y`, containing the coordinates of the last point on each of the curves (but not the confidence limits). This may be useful for labeling.

### Note

In prior versions the behavior of `xscale` and `yscale` differed: the first changed the scale both for the plot and for all subsequent actions such as adding a legend, whereas `yscale` affected only the axis label. This was normalized in version 2-36.4, and both parameters now only affect the labeling.

### Examples

```
leukemia.surv <- survfit(Surv(time, status) ~ x, data = aml)
plot(leukemia.surv, lty = 2:3)
legend(100, .9, c("Maintenance", "No Maintenance"), lty = 2:3)
title("Kaplan-Meier Curves\nfor AML Maintenance Study")
lsurv2 <- survfit(Surv(time, status) ~ x, aml, type='fleming')
plot(lsurv2, lty=2:3, fun="cumhaz",
     xlab="Months", ylab="Cumulative Hazard")
```

---

predict.coxph

*Predictions for a Cox model*

---

### Description

Compute fitted values and regression terms for a model fitted by [coxph](#)

### Usage

```
## S3 method for class 'coxph'
predict(object, newdata,
  type=c("lp", "risk", "expected", "terms", "survival"),
  se.fit=FALSE, na.action=na.pass, terms=names(object$assign), collapse,
  reference=c("strata", "sample"), ...)
```

**Arguments**

|                        |  |
|------------------------|--|
| <code>object</code>    | the results of a coxph fit.  |
| <code>newdata</code>   | Optional new data at which to do predictions. If absent predictions are for the data frame used in the original fit. When coxph has been called with a formula argument created in another context, i.e., coxph has been called within another function and the formula was passed as an argument to that function, there can be problems finding the data set. See the note below.      |
| <code>type</code>      | the type of predicted value. Choices are the linear predictor (" <code>lp</code> "), the risk score $\exp(lp)$ (" <code>risk</code> "), the expected number of events given the covariates and follow-up time (" <code>expected</code> "), and the terms of the linear predictor (" <code>terms</code> "). The survival probability for a subject is equal to $\exp(-\text{expected})$ . |
| <code>se.fit</code>    | if TRUE, pointwise standard errors are produced for the predictions.   |
| <code>na.action</code> | applies only when the newdata argument is present, and defines the missing value action for the new data. The default is to include all observations. When there is no newdata, then the behavior of missing is dictated by the na.action option of the original fit.  |
| <code>terms</code>     | if type="terms", this argument can be used to specify which terms should be included; the default is all.  |
| <code>collapse</code>  | optional vector of subject identifiers. If specified, the output will contain one entry per subject rather than one entry per observation.   |
| <code>reference</code> | reference for centering predictions, see details below   |
| <code>...</code>       | For future methods   |

**Details**

The Cox model is a *relative* risk model; predictions of type "linear predictor", "risk", and "terms" are all relative to the sample from which they came. By default, the reference value for each of these is the mean covariate within strata. The primary underlying reason is statistical: a Cox model only predicts relative risks between pairs of subjects within the same strata, and hence the addition of a constant to any covariate, either overall or only within a particular stratum, has no effect on the fitted results. Using the `reference="strata"` option causes this to be true for predictions as well.

When the results of predict are used in further calculations it may be desirable to use a fixed reference level. Use of `reference="sample"` will use the overall means, and agrees with the `linear.predictors` component of the coxph object (which uses the overall mean for backwards compatibility with older code). Predictions of type="terms" are almost invariably passed forward to further calculation, so for these we default to using the sample as the reference.

Predictions of type "expected" incorporate the baseline hazard and are thus absolute instead of relative; the reference option has no effect on these.

Models that contain a frailty term are a special case: due to the technical difficulty, when there is a newdata argument the predictions will always be for a random effect of zero.

**Value**

a vector or matrix of predictions, or a list containing the predictions (element "`fit`") and their standard errors (element "`se.fit`") if the `se.fit` option is TRUE.

**Note**

Some predictions can be obtained directly from the `coxph` object, and for others it is necessary for the routine to have the entirety of the original data set, e.g., for `type = terms` or if standard errors are requested. This extra information is saved in the `coxph` object if `model=TRUE`, if not the original data is reconstructed. If it is known that such residuals will be required overall execution will be slightly faster if the model information is saved.

In some cases the reconstruction can fail. The most common is when `coxph` has been called inside another function and the formula was passed as one of the arguments to that enclosing function. Another is when the data set has changed between the original call and the time of the prediction call. In each of these the simple solution is to add `model=TRUE` to the original `coxph` call.

**Examples**

```
options(na.action=na.exclude) # retain NA in predictions
fit <- coxph(Surv(time, status) ~ age + ph.ecog + strata(inst), lung)
#lung data set has status coded as 1/2
mresid <- (lung$status-1) - predict(fit, type='expected') #Martingale resid
predict(fit,type="lp")
predict(fit,type="expected")
predict(fit,type="risk",se.fit=TRUE)
predict(fit,type="terms",se.fit=TRUE)
```

---

|                 |  |
|-----------------|--|
| predict.survreg | <i>Predicted Values for a 'survreg' Object</i> |
|-----------------|--|

---

**Description**

Predicted values for a `survreg` object

**Usage**

```
## S3 method for class 'survreg'
predict(object, newdata,
  type=c("response", "link", "lp", "linear", "terms", "quantile",
    "uquantile"),
  se.fit=FALSE, terms=NULL, p=c(0.1, 0.9), na.action=na.pass, ...)
```

**Arguments**

|                      |  |
|----------------------|--|
| <code>object</code>  | result of a model fit using the <code>survreg</code> function.   |
| <code>newdata</code> | data for prediction. If absent predictions are for the subjects used in the original fit.  |
| <code>type</code>    | the type of predicted value. This can be on the original scale of the data (response), the linear predictor ("linear", with "lp" as an allowed abbreviation), a predicted quantile on the original scale of the data ("quantile"), a quantile on the linear predictor scale ("uquantile"), or the matrix of terms for the linear predictor ("terms"). At this time "link" and linear predictor ("lp") are identical. |

|           |   |
|-----------|---|
| se.fit    | if TRUE, include the standard errors of the prediction in the result.   |
| terms     | subset of terms. The default for residual type "terms" is a matrix with one column for every term (excluding the intercept) in the model.             |
| p         | vector of percentiles. This is used only for quantile predictions.  |
| na.action | applies only when the newdata argument is present, and defines the missing value action for the new data. The default is to include all observations. |
| ...       | for future methods  |

### Value

a vector or matrix of predicted values.

### Description

Print out a fit of Aalen's additive regression model

**Usage**

```
## S3 method for class 'aareg'
print(x, maxtime, test=c("aalen", "nrisk"), scale=1, ...)
```

**Arguments**

|         |   |
|---------|---|
| x       | the result of a call to the aareg function  |
| maxtime | the upper time point to be used in the test for non-zero slope  |
| test    | the weighting to be used in the test for non-zero slope. The default weights are based on the variance of each coefficient, as a function of time. The alternative weight is proportional to the number of subjects still at risk at each time point. |
| scale   | scales the coefficients. For some data sets, the coefficients of the Aalen model will be very small (10 <sup>-4</sup> ); this simply multiplies the printed values by a constant, say 1e6, to make the printout easier to read.                       |
| ...     | for future methods  |

**Details**

The estimated increments in the coefficient estimates can become quite unstable near the end of follow-up, due to the small number of observations still at risk in a data set. Thus, the test for slope will sometimes be more powerful if this last 'tail' is excluded.

**Value**

the calling argument is returned.

**Side Effects**

the results of the fit are displayed.

Print number of observations, number of events, the restricted mean survival and its standard error, and the median survival with confidence limits for the median.

### Usage

```
## S3 method for class 'survfit'
print(x, scale=1, digits = max(options())$digits - 4, 3),
      print.rmean=getOption("survfit.print.rmean"),
      rmean = getOption('survfit.rmean'),...)
```

**Arguments**

|                    |   |
|--------------------|---|
| x                  | the result of a call to the <code>survfit</code> function.  |
| scale              | a numeric value to rescale the survival time, e.g., if the input data to <code>survfit</code> were in days, <code>scale=365</code> would scale the printout to years. |
| digits             | Number of digits to print   |
| print.rmean, rmean | Options for computation and display of the restricted mean.   |
| ...                | for future results  |

**Details**

The mean and its variance are based on a truncated estimator. That is, if the last observation(s) is not a death, then the survival curve estimate does not go to zero and the mean is undefined. There are four possible approaches to resolve this, which are selected by the `rmean` option. The first is to set the upper limit to a constant, e.g., `rmean=365`. In this case the reported mean would be the expected number of days, out of the first 365, that would be experienced by each group. This is useful if interest focuses on a fixed period. Other options are "none" (no estimate), "common" and "individual". The "common" option uses the maximum time for all curves in the object as a common upper limit for the auc calculation. For the "individual" options the mean is computed as the area under each curve, over the range from 0 to the maximum observed time for that curve. Since the end point is random, values for different curves are not comparable and the printed standard errors are an underestimate as they do not take into account this random variation. This option is provided mainly for backwards compatibility, as this estimate was the default (only) one in earlier releases of the code. Note that SAS (as of version 9.3) uses the integral up to the last *event* time of each individual curve; we consider this the worst of the choices and do not provide an option for that calculation.

The median and its confidence interval are defined by drawing a horizontal line at 0.5 on the plot of the survival curve and its confidence bands. The intersection of the line with the lower CI band defines the lower limit for the median's interval, and similarly for the upper band. If any of the intersections is not a point, then we use the smallest point of intersection, e.g., if the survival curve were exactly equal to 0.5 over an interval.

**Value**

x, with the invisible flag set to prevent printing. (The default for all print functions in R is to return the object passed to them; `print.survfit` complies with this pattern. If you want to capture these printed results for further processing, see the `table` component of `summary.survfit`.)

**Side Effects**

The number of observations, the number of events, the median survival with its confidence interval, and optionally the restricted mean survival (`rmean`) and its standard error, are printed. If there are multiple curves, there is one line of output for each.

**See Also**

[summary.survfit](#), [quantile.survfit](#)

## Description

Specifies a penalised spline basis for the predictor. This is done by fitting a comparatively small set of splines and penalising the integrated second derivative. Traditional smoothing splines use one basis per observation, but several authors have pointed out that the final results of the fit are indistinguishable for any number of basis functions greater than about 2-3 times the degrees of freedom. Eilers and Marx point out that if the basis functions are evenly spaced, this leads to significant computational simplification, they refer to the result as a p-spline.

## Usage

```
pspline(x, df=4, theta, nterm=2.5 * df, degree=3, eps=0.1, method,
        Boundary.knots=range(x), intercept=FALSE, penalty=TRUE, combine, ...)
```

```
psplineinverse(x)
```

## Arguments

|                |   |
|----------------|---|
| x              | for pspline: a covariate vector. The function does not apply to factor variables. For psplineinverse x will be the result of a pspline call.  |
| df             | the desired degrees of freedom. One of the arguments df or theta' must be given, but not both. If df=0, then the AIC = (loglik -df) is used to choose an "optimal" degrees of freedom. If AIC is chosen, then an optional argument 'caic=T' can be used to specify the corrected AIC of Hurvich et. al. |
| theta          | roughness penalty for the fit. It is a monotone function of the degrees of freedom, with theta=1 corresponding to a linear fit and theta=0 to an unconstrained fit of nterm degrees of freedom.   |
| nterm          | number of splines in the basis  |
| degree         | degree of splines   |
| eps            | accuracy for df   |
| method         | the method for choosing the tuning parameter theta. If theta is given, then 'fixed' is assumed. If the degrees of freedom is given, then 'df' is assumed. If method='aic' then the degrees of freedom is chosen automatically using Akaike's information criterion.                                     |
| ...            | optional arguments to the control function  |
| Boundary.knots | the spline is linear beyond the boundary knots. These default to the range of the data.   |
| intercept      | if TRUE, the basis functions include the intercept.   |
| penalty        | if FALSE a large number of attributes having to do with penalized fits are excluded. This is useful to create a pspline basis matrix for other uses.  |
| combine        | an optional vector of increasing integers. If two adjacent values of combine are equal, then the corresponding coefficients of the fit are forced to be equal. This is useful for monotone fits, see the vignette for more details.   |

**Value**

Object of class `pspline`, `coxph.penalty` containing the spline basis, with the appropriate attributes to be recognized as a penalized term by the `coxph` or `survreg` functions.

For `psplineinverse` the original `x` vector is reconstructed.

---

|                     |                     |
|---------------------|---------------------|
| <code>pyears</code> | <i>Person Years</i> |
|---------------------|---------------------|

---

**Description**

This function computes the person-years of follow-up time contributed by a cohort of subjects, stratified into subgroups. It also computes the number of subjects who contribute to each cell of the output table, and optionally the number of events and/or expected number of events in each cell.

**Usage**

```
pyears(formula, data, weights, subset, na.action, rmap,
       ratetable, scale=365.25, expect=c('event', 'pyears'),
       model=FALSE, x=FALSE, y=FALSE, data.frame=FALSE)
```

**Arguments**

|                      |  |
|----------------------|--|
| <code>formula</code> | a formula object. The response variable will be a vector of follow-up times for each subject, or a <code>Surv</code> object containing the survival time and an event indicator. The predictors consist of optional grouping variables separated by <code>+</code> operators (exactly as in <code>survfit</code> ), time-dependent grouping variables such as <code>age</code> (specified with <code>tcut</code> ), and optionally a <code>ratetable</code> term. This latter matches each subject to his/her expected cohort. |
|----------------------|--|

|                          |   |
|--------------------------|---|
| <code>data</code>        | a data frame in which to interpret the variables named in the formula, or in the subset and the weights argument.   |
| <code>weights</code>     | case weights.   |
| <code>subset</code>      | expression saying that only a subset of the rows of the data should be used in the fit.   |
| <code>na.action</code>   | a missing-data filter function, applied to the model.frame, after any subset argument has been used. Default is <code>options()\$na.action</code> .         |
| <code>rmap</code>        | an optional list that maps data set names to the ratetable names. See the details section below.  |
| <code>ratetable</code>   | a table of event rates, such as <code>survexp.uswhite</code> .  |
| <code>scale</code>       | a scaling for the results. As most rate tables are in units/day, the default value of 365.25 causes the output to be reported in years.                     |
| <code>expect</code>      | should the output table include the expected number of events, or the expected number of person-years of observation. This is only valid with a rate table. |
| <code>data.frame</code>  | return a data frame rather than a set of arrays.  |
| <code>model, x, y</code> | If any of these is true, then the model frame, the model matrix, and/or the vector of response times will be returned as components of the final result.    |

### Details

Because `pyears` may have several time variables, it is necessary that all of them be in the same units. For instance, in the call

```
py <- pyears(futime ~ rx, rmap=list(age=age, sex=sex, year=entry.dt),
             ratetable=survexp.us)
```

the natural unit of the `ratetable` is hazard per day, it is important that `futime`, `age` and `entry.dt` all be in days. Given the wide range of possible inputs, it is difficult for the routine to do sanity checks of this aspect.

The `ratetable` being used may have different variable names than the user's data set, this is dealt with by the `rmap` argument. The rate table for the above calculation was `survexp.us`, a call to `summary{survexp.us}` reveals that it expects to have variables `age` = age in days, `sex`, and `year` = the date of study entry, we create them in the `rmap` line. The `sex` variable is not mapped, therefore the code assumes that it exists in `mydata` in the correct format. (Note: for factors such as `sex`, the program will match on any unique abbreviation, ignoring case.)

A special function `tcut` is needed to specify time-dependent cutpoints. For instance, assume that `age` is in years, and that the desired final arrays have as one of their margins the age groups 0-2, 2-10, 10-25, and 25+. A subject who enters the study at age 4 and remains under observation for 10 years will contribute follow-up time to both the 2-10 and 10-25 subsets. If `cut(age, c(0,2,10,25,100))` were used in the formula, the subject would be classified according to his starting age only. The `tcut` function has the same arguments as `cut`, but produces a different output object which allows the `pyears` function to correctly track the subject.

The results of `pyears` are normally used as input to further calculations. The `print` routine, therefore, is designed to give only a summary of the table.

### Value

a list with components:

|                           |   |
|---------------------------|---|
| <code>pyears</code>       | an array containing the person-years of exposure. (Or other units, depending on the rate table and the scale). The dimension and dimnames of the array correspond to the variables on the right hand side of the model equation.  |
| <code>n</code>            | an array containing the number of subjects who contribute time to each cell of the <code>pyears</code> array.   |
| <code>event</code>        | an array containing the observed number of events. This will be present only if the response variable is a <code>Surv</code> object.  |
| <code>expected</code>     | an array containing the expected number of events (or person years if <code>expect = "pyears"</code> ). This will be present only if there was a <code>ratetable</code> term.   |
| <code>data</code>         | if the <code>data.frame</code> option was set, a data frame containing the variables <code>n</code> , <code>event</code> , <code>pyears</code> and <code>event</code> that supplants the four arrays listed above, along with variables corresponding to each dimension. There will be one row for each cell in the arrays. |
| <code>offtable</code>     | the number of person-years of exposure in the cohort that was not part of any cell in the <code>pyears</code> array. This is often useful as an error check; if there is a mismatch of units between two variables, nearly all the person years may be off table.   |
| <code>tcut</code>         | whether the call included any time-dependent cutpoints.   |
| <code>summary</code>      | a summary of the rate-table matching. This is also useful as an error check.  |
| <code>call</code>         | an image of the call to the function.   |
| <code>observations</code> | the number of observations in the input data set, after any missings were removed.  |
| <code>na.action</code>    | the <code>na.action</code> attribute contributed by an <code>na.action</code> routine, if any.  |

|------------------|--|
| quantile.survfit | <i>Quantiles from a survfit object</i> |
|------------------|--|

---

## Description

Retrieve quantiles and confidence intervals for them from a survfit object.

## Usage

```

## S3 method for class 'survfit'
quantile(x, probs = c(0.25, 0.5, 0.75), conf.int = TRUE,
         tolerance= sqrt(.Machine$double.eps), ...)
## S3 method for class 'survfitms'
quantile(x, probs = c(0.25, 0.5, 0.75), conf.int = TRUE,
         tolerance= sqrt(.Machine$double.eps), ...)

```

## Arguments

|           |  |
|-----------|--|
| x         | a result of the survfit function   |
| probs     | numeric vector of probabilities with values in [0,1]                               |
| conf.int  | should lower and upper confidence limits be returned?                              |
| tolerance | tolerance for checking that the survival curve exactly equals one of the quantiles |
| ...       | optional arguments for other methods   |

## Details

The  $k$ th quantile for a survival curve  $S(t)$  is the location at which a horizontal line at height  $p=1-k$  intersects the plot of  $S(t)$ . Since  $S(t)$  is a step function, it is possible for the curve to have a horizontal segment at exactly  $1-k$ , in which case the midpoint of the horizontal segment is returned. This mirrors the standard behavior of the median when data is uncensored. If the survival curve does not fall to  $1-k$ , then that quantile is undefined.

In order to be consistent with other quantile functions, the argument `prob` of this function applies to the cumulative distribution function  $F(t) = 1-S(t)$ .

Confidence limits for the values are based on the intersection of the horizontal line at  $1-k$  with the upper and lower limits for the survival curve. Hence confidence limits use the same  $p$ -value as was in effect when the curve was created, and will differ depending on the `conf.type` option of `survfit`. If the survival curves have no confidence bands, confidence limits for the quantiles are not available.

When a horizontal segment of the survival curve exactly matches one of the requested quantiles the returned value will be the midpoint of the horizontal segment; this agrees with the usual definition of a median for uncensored data. Since the survival curve is computed as a series of products, however, there may be round off error. Assume for instance a sample of size 20 with no tied times and no censoring. The survival curve after the 10th death is  $(19/20)(18/19)(17/18) \dots (10/11) = 10/20$ , but the computed result will not be exactly 0.5. Any horizontal segment whose absolute difference with a requested percentile is less than tolerance is considered to be an exact match.

### Value

The quantiles will be a vector if the `survfit` object contains only a single curve, otherwise it will be a matrix or array. In this case the last dimension will index the quantiles.

If confidence limits are requested, then result will be a list with components `quantile`, `lower`, and `upper`, otherwise it is the vector or matrix of quantiles.

|               |   |
|---------------|---|
| ratetableDate | <i>Convert date objects to ratetable form</i> |
|---------------|---|

---

**Description**

This method converts dates from various forms into the internal form used in `ratetable` objects.

**Usage**

```
ratetableDate(x)
```

**Arguments**

`x` a date. The function currently has methods for `Date`, `date`, `POSIXt`, `timeDate`, and `chron` objects.

**Details**

This function is useful for those who create new `ratetables`, but is normally invisible to users. It is used internally by the `survexp` and `pyears` functions to map the various date formats; if a new method is added then those routines will automatically be adapted to the new date type.

**Value**

a numeric vector, the number of days since 1/1/1960.

**Author(s)**

Terry Therneau

ratetables

*Census Data Sets for the Expected Survival and Person Years Functions*

---

### Description

Census data sets for the expected survival and person years functions.

### Details

**us** total United States population, by age and sex, 1940 to 2004.

**usr** United States population, by age, sex and race, 1940 to 2004. Race is white, nonwhite, or black. For 1960 and 1970 the black population values were not reported separately, so the nonwhite values were used.

**mn** total Minnesota population, by age and sex, 1970 to 2004.

Each of these tables contains the daily hazard rate for a matched subject from the population, defined as  $-\log(1 - q)/365.25$  where  $q$  is the 1 year probability of death as reported in the original tables. For age 25 in 1970, for instance,  $p = 1 - q$  is the probability that a subject who becomes 25 years of age in 1970 will achieve his/her 26th birthday. The tables are recast in terms of hazard per day entirely for computational convenience.

Each table is stored as an array, with additional attributes, and can be subset and manipulated as standard R arrays.

### Examples

```
survexp.uswhite <- survexp.usr[,,"white",]
```

rats

*Rat treatment data from Mantel et al*

---

### Description

Rat treatment data from Mantel et al. Three rats were chosen from each of 100 litters, one of which was treated with a drug, and then all followed for tumor incidence.

### Usage

```
rats
```

### Format

```
litter:  litter number from 1 to 100
rx:      treatment,(1=drug, 0=control)
time:    time to tumor or last follow-up
status:  event status, 1=tumor and 0=censored
sex:     male or female
```

**Note**

Since only 2/150 of the male rats have a tumor, most analyses use only females (odd numbered litters), e.g. Lee et al.

residuals.coxph

*Calculate Residuals for a 'coxph' Fit***Description**

Calculates martingale, deviance, score or Schoenfeld residuals for a Cox proportional hazards model.

**Usage**

```
## S3 method for class 'coxph'
residuals(object,
  type=c("martingale", "deviance", "score", "schoenfeld",
    "dfbeta", "dfbetas", "scaledsch", "partial"),
  collapse=FALSE, weighted=FALSE, ...)
## S3 method for class 'coxph.null'
residuals(object,
  type=c("martingale", "deviance", "score", "schoenfeld"),
  collapse=FALSE, weighted=FALSE, ...)
```

**Arguments**

|          |   |
|----------|---|
| object   | an object inheriting from class coxph, representing a fitted Cox regression model. Typically this is the output from the coxph function.  |
| type     | character string indicating the type of residual desired. Possible values are "martingale", "deviance", "score", "schoenfeld", "dfbeta", "dfbetas", and "scaledsch". Only enough of the string to determine a unique match is required.   |
| collapse | vector indicating which rows to collapse (sum) over. In time-dependent models more than one row data can pertain to a single individual. If there were 4 individuals represented by 3, 1, 2 and 4 rows of data respectively, then collapse=c(1,1,1, 2, 3,3, 4,4,4,4) could be used to obtain per subject rather than per observation residuals. |
| weighted | if TRUE and the model was fit with case weights, then the weighted residuals are returned.  |
| ...      | other unused arguments  |

**Value**

For martingale and deviance residuals, the returned object is a vector with one element for each subject (without collapse). For score residuals it is a matrix with one row per subject and one column per variable. The row order will match the input data for the original fit. For Schoenfeld residuals, the returned object is a matrix with one row for each event and one column per variable. The rows are ordered by time within strata, and an attribute strata is attached that contains the number of observations in each strata. The scaled Schoenfeld residuals are used in the cox.zph function.

The score residuals are each individual's contribution to the score vector. Two transformations of this are often more useful: dfbeta is the approximate change in the coefficient vector if that observation were dropped, and dfbetas is the approximate change in the coefficients, scaled by the standard error for the coefficients.

NOTE

For deviance residuals, the status variable may need to be reconstructed. For score and Schoenfeld residuals, the X matrix will need to be reconstructed.

[coxph](#)

Examples

```
fit <- coxph(Surv(start, stop, event) ~ (age + surgery)* transplant,
             data=heart)
mresid <- resid(fit, collapse=heart$id)
```

---

|                   |  |
|-------------------|--|
| residuals.survreg | <i>Compute Residuals for 'survreg' Objects</i> |
|-------------------|--|

---

Description

This is a method for the function [residuals](#) for objects inheriting from class `survreg`.

Usage

```
## S3 method for class 'survreg'
residuals(object, type=c("response", "deviance", "dfbeta", "dfbetas",
"working", "ldcase", "ldresp", "ldshape", "matrix"), rsigma=TRUE,
collapse=FALSE, weighted=FALSE, ...)
```

Arguments

|          |  |
|----------|--|
| object   | an object inheriting from class <code>survreg</code> .   |
| type     | type of residuals, with choices of "response", "deviance", "dfbeta", "dfbetas", "working", "ldcase", "lsresp", "ldshape", and "matrix". See the LaTeX documentation ( <a href="#">survival/doc/survival.ps.gz</a> ) for more detail. |
| rsigma   | include the scale parameters in the variance matrix, when doing computations. (I can think of no good reason not to).  |
| collapse | optional vector of subject groups. If given, this must be of the same length as the residuals, and causes the result to be per group residuals.  |
| weighted | give weighted residuals? Normally residuals are unweighted.  |
| ...      | other unused arguments   |

Value

A vector or matrix of residuals is returned. Response residuals are on the scale of the original data, working residuals are on the scale of the linear predictor, and deviance residuals are on log-likelihood scale. The dfbeta residuals are a matrix, where the *i*th row gives the approximate change in the coefficients due to the addition of subject *i*. The dfbetas matrix contains the dfbeta residuals, with each column scaled by the standard deviation of that coefficient.

The matrix type produces a matrix based on derivatives of the log-likelihood function. Let *L* be the log-likelihood, *p* be the linear predictor  $X\beta$ , and *s* be  $\log(\sigma)$ . Then the 6 columns of the matrix are *L*,  $dL/dp$ ,  $\partial^2 L/\partial p^2$ ,  $dL/ds$ ,  $\partial^2 L/\partial s^2$  and  $\partial^2 L/\partial p \partial s$ . Diagnostics based on these quantities are discussed in an article by Escobar and Meeker. The main ones are the likelihood displacement residuals for perturbation of a case weight (ldcase), the response value (ldresp), and the shape.

|-------------|-----------------------------|
| retinopathy | <i>Diabetic Retinopathy</i> |
|-------------|-----------------------------|

---

Description

A trial of laser coagulation as a treatment to delay diabetic retinopathy.

Usage

```
data("retinopathy")
```

Format

A data frame with 394 observations on the following 9 variables.

id numeric subject id

laser type of laser used: xenon argon

eye which eye was treated: right left

age age at diagnosis of diabetes

type type of diabetes: juvenile adult, (diagnosis before age 20)

trt 0 = control eye, 1 = treated eye

futime time to loss of vision or last follow-up

status 0 = censored, 1 = loss of vision in this eye

risk a risk score for the eye. This high risk subset is defined as a score of 6 or greater in at least one eye.

## Details

The 197 patients in this dataset were a 50% random sample of the patients with "high-risk" diabetic retinopathy as defined by the Diabetic Retinopathy Study (DRS). Each patient had one eye randomized to laser treatment and the other eye received no treatment, and has two observations in the data set. For each eye, the event of interest was the time from initiation of treatment to the time when visual acuity dropped below 5/200 two visits in a row. Thus there is a built-in lag time of approximately 6 months (visits were every 3 months). Survival times in this dataset are the actual time to vision loss in months, minus the minimum possible time to event (6.5 months). Censoring was caused by death, dropout, or end of the study.

|---------|-------------------------|
| rhDNase | <i>rhDNASE data set</i> |
|---------|-------------------------|

---

## Description

Results of a randomized trial of rhDNase for the treatment of cystic fibrosis.

## Format

A data frame with 767 observations on the following 8 variables.

id subject id  
 inst enrolling institution  
 trt treatment arm: 0=placebo, 1= rhDNase  
 entry.dt date of entry into the study  
 end.dt date of last follow-up  
 fev forced expiratory volume at enrollment, a measure of lung capacity  
 ivstart days from enrollment to the start of IV antibiotics  
 ivstop days from enrollment to the cessation of IV antibiotics

## Details

In patients with cystic fibrosis, extracellular DNA is released by leukocytes that accumulate in the airways in response to chronic bacterial infection. This excess DNA thickens the mucus, which then cannot be cleared from the lung by the cilia. The accumulation leads to exacerbations of respiratory symptoms and progressive deterioration of lung function. At the time of this study more than 90% of cystic fibrosis patients eventually died of lung disease.

Deoxyribonuclease I (DNase I) is a human enzyme normally present in the mucus of human lungs that digests extracellular DNA. Genentech, Inc. cloned a highly purified recombinant DNase I (rhDNase or Pulmozyme) which when delivered to the lungs in an aerosolized form cuts extracellular DNA, reducing the viscoelasticity of airway secretions and improving clearance. In 1992 the company conducted a randomized double-blind trial comparing rhDNase to placebo. Patients were then monitored for pulmonary exacerbations, along with measures of lung volume and flow. The primary endpoint was the time until first pulmonary exacerbation; however, data on all exacerbations were collected for 169 days.

The definition of an exacerbation was an infection that required the use of intravenous (IV) antibiotics. Subjects had 0–5 such episodes during the trial, those with more than one have multiple rows in the data set, those with none have NA for the IV start and end times. A few subjects were infected at the time of enrollment, subject 173 for instance has a first infection interval of -21 to 7. We do not count this first infection as an "event", and the subject first enters the risk set at day 7. Subjects who have an event are not considered to be at risk for another event during the course of antibiotics, nor for an additional 6 days after they end. (If the symptoms reappear immediately after cessation then from a medical standpoint this would not be a new infection.)

This data set reproduces the data in Therneau and Grambsch, it does not exactly reproduce those in Therneau and Hamilton due to data set updates.

## Examples

```
# Build the start-stop data set for analysis, and
# replicate line 2 of table 8.13
first <- subset(rhDNase, !duplicated(id)) #first row for each subject
dnase <- tmerge(first, first, id=id, tstop=as.numeric(end.dt -entry.dt))

# Subjects whose fu ended during the 6 day window are the reason for
# this next line
temp.end <- with(rhDNase, pmin(ivstop+6, end.dt-entry.dt))
dnase <- tmerge(dnase, rhDNase, id=id,
               infect=event(ivstart),
               end= event(temp.end))
# toss out the non-at-risk intervals, and extra variables
# 3 subjects had an event on their last day of fu, infect=1 and end=1
dnase <- subset(dnase, (infect==1 | end==0), c(id:trt, fev:infect))
agfit <- coxph(Surv(tstart, tstop, infect) ~ trt + fev + cluster(id),
               data=dnase)
```

## Description

When used in a [coxph](#) or [survreg](#) model formula, specifies a ridge regression term. The likelihood is penalised by  $\text{theta}/2$  time the sum of squared coefficients. If `scale=T` the penalty is calculated for coefficients based on rescaling the predictors to have unit variance. If `df` is specified then `theta` is chosen based on an approximate degrees of freedom.

## Usage

```
ridge(..., theta, df=nvar/2, eps=0.1, scale=TRUE)
```

## Arguments

|                    |  |
|--------------------|--|
| <code>...</code>   | predictors to be ridged                                      |
| <code>theta</code> | penalty is $\text{theta}/2$ time sum of squared coefficients |
| <code>df</code>    | Approximate degrees of freedom                               |
| <code>eps</code>   | Accuracy required for <code>df</code>                        |
| <code>scale</code> | Scale variables before applying penalty?                     |

## Value

An object of class `coxph.penalty` containing the data and control functions.

statefig*Draw a state space figure.*

---

**Description**

For multi-state survival models it is useful to have a figure that shows the states and the possible transitions between them. This function creates a simple "box and arrows" figure. It's goal was simplicity.

**Usage**

```
statefig(layout, connect, margin = 0.03, box = TRUE, cex = 1, col = 1,  
         lwd=1, lty=1, bcol=col, acol=col, alwd=lwd, alty=lty)
```

**Arguments**

|                    |   |
|--------------------|---|
| layout             | describes the layout of the boxes on the page. See the detailed description below.  |
| connect            | a square matrix with one row for each state. If <code>connect[i, j] != 0</code> then an arrow is drawn from state <i>i</i> to state <i>j</i> . The row names of the matrix are used as the labels for the states. |
| margin             | the fraction of white space between the label and the surrounding box, and between the box and the arrows, as a function of the plot region size.   |
| box                | should boxes be drawn? TRUE or FALSE.   |
| cex, col, lty, lwd | default graphical parameters used for the text and boxes. The last 3 can be a vector of values.   |
| bcol               | color for the box, if it differs from that used for the text.   |
| acol, alwd, alty   | color, line type and line width for the arrows. Only the first element is used.   |

**Details**

The layout argument is normally a vector of integers, e.g., the vector (1, 3, 2) describes a layout with 3 columns. The first has a single state, the second column has 3 states and the third has 2. The coordinates of the plotting region are 0 to 1 for both x and y. Within a column the centers of the boxes are evenly spaced, with 1/2 a space between the boxes and the margin, e.g., 4 boxes would be at 1/8, 3/8, 5/8 and 7/8. If layout were a 1 column matrix with values of (1, 3, 2) then the layout will have three rows with 1, 3, and 2 boxes per row, respectively. Alternatively, the user can supply a 2 column matrix that directly gives the centers.

The values of the connect matrix should be 0 for pairs of states that do not have a transition and values between 0 and 2 for those that do. States are connected by an arc that passes through the centers of the two boxes and a third point that is between them. Specifically, consider a line segment joining the two centers and erect a second segment at right angles to the midpoint of length *d* times the distance from center to midpoint. The arc passes through this point. A value of *d*=0 gives a straight line, *d*=1 a right hand half circle centered on the midpoint and *d*= -1 a left hand half circle. The connect matrix contains values of *d*+1 with  $-1 < d < 1$ .

**Value**

a matrix containing the centers of the boxes, with the invisible attribute set.

**Note**

The goal of this function is to make “good enough” figures as simply as possible, and thereby to encourage users to draw them. The layout argument was inspired by the diagram package, which can draw more complex and well decorated figures, e.g., many different shapes, shading, multiple types of connecting lines, etc., but at the price of greater complexity.

**Author(s)**

Terry Therneau

**Examples**

```
# Draw a simple competing risks figure
states <- c("Entry", "Complete response", "Relapse", "Death")
connect <- matrix(0, 4, 4, dimnames=list(states, states))
connect[1, -1] <- c(1.1, 1, 0.9)
statefig(c(1, 3), connect)
```

strata

*Identify Stratification Variables***Description**

This is a special function used in the context of the Cox survival model. It identifies stratification variables when they appear on the right hand side of a formula.

**Usage**

```
strata(..., na.group=FALSE, shortlabel, sep=', ')
```

**Arguments**

|                         |  |
|-------------------------|--|
| <code>...</code>        | any number of variables. All must be the same length.  |
| <code>na.group</code>   | a logical variable, if TRUE, then missing values are treated as a distinct level of each variable.   |
| <code>shortlabel</code> | if TRUE omit variable names from resulting factor labels. The default action is to omit the names if all of the arguments are factors, and none of them was named. |
| <code>sep</code>        | the character used to separate groups, in the created label  |

**Details**

The result is identical to the interaction function, but for the labeling of the factors (strata is more verbose).

**Value**

a new factor, whose levels are all possible combinations of the factors supplied as arguments.

**See Also**

[coxph](#), [interaction](#)

**Examples**

```
a <- factor(rep(1:3,4), labels=c("low", "medium", "high"))
b <- factor(rep(1:4,3))
levels(strata(b))
levels(strata(a,b,shortlabel=TRUE))

coxph(Surv(futime, fustat) ~ age + strata(rx), data=ovarian)
```

|---------------|-------------------------------|
| summary.aareg | <i>Summarize an aareg fit</i> |
|---------------|-------------------------------|

---

## Description

Creates the overall test statistics for an Aalen additive regression model

## Usage

```
## S3 method for class 'aareg'
summary(object, maxtime, test=c("aalen", "nrisk"), scale=1,...)
```

## Arguments

|         |   |
|---------|---|
| object  | the result of a call to the aareg function  |
| maxtime | truncate the input to the model at time "maxtime"   |
| test    | the relative time weights that will be used to compute the test   |
| scale   | scales the coefficients. For some data sets, the coefficients of the Aalen model will be very small (10 <sup>-4</sup> ); this simply multiplies the printed values by a constant, say 1e6, to make the printout easier to read. |
| ...     | for future methods  |

## Details

It is not uncommon for the very right-hand tail of the plot to have large outlying values, particularly for the standard error. The maxtime parameter can then be used to truncate the range so as to avoid these. This gives an updated value for the test statistics, without refitting the model.

The slope is based on a weighted linear regression to the cumulative coefficient plot, and may be a useful measure of the overall size of the effect. For instance when two models include a common variable, "age" for instance, this may help to assess how much the fit changed due to the other variables, in lieu of overlaying the two plots. (Of course the plots are often highly non-linear, so it is only a rough substitute). The slope is not directly related to the test statistic, as the latter is invariant to any monotone transformation of time.

## Value

a list is returned with the following components

|                |  |
|----------------|--|
| table          | a matrix with rows for the intercept and each covariate, and columns giving a slope estimate, the test statistic, it's standard error, the z-score and a p-value |
| test           | the time weighting used for computing the test statistics  |
| test.statistic | the vector of test statistics  |
| test.var       | the model based variance matrix for the test statistic   |
| test.var2      | optionally, a robust variance matrix for the test statistic  |
| chisq          | the overall test (ignoring the intercept term) for significance of any variable  |
| n              | a vector containing the number of observations, the number of unique death times used in the computation, and the total number of unique death times             |

summary.pyears

*Summary function for pyears objects*

---

**Description**

Create a printable table of a person-years result.

**Usage**

```
## S3 method for class 'pyears'
summary(object, header = TRUE, call = header, n = TRUE,
event = TRUE, pyears = TRUE, expected = TRUE, rate = FALSE, rr = expected,
ci.r = FALSE, ci.rr = FALSE, totals=FALSE, legend = TRUE, vline = FALSE,
vertical= TRUE, nastring=".", conf.level = 0.95,
scale = 1, ...)
```

**Arguments**

|  |   |
|--|---|
| <code>object</code>                      | a pyyears object  |
| <code>header</code>                      | print out a header giving the total number of observations, events, person-years, and total time (if any) omitted from the table  |
| <code>call</code>                        | print out a copy of the call  |
| <code>n, event, pyyears, expected</code> | logical arguments: should these elements be printed in the table?   |
| <code>rate, ci.r</code>                  | logical arguments: should the incidence rate and/or its confidence interval be given in the table?  |
| <code>rr, ci.rr</code>                   | logical arguments: should the hazard ratio and/or its confidence interval be given in the table?  |
| <code>totals</code>                      | should row and column totals be added?  |
| <code>legend</code>                      | should a legend be included in the printout?  |
| <code>vline</code>                       | should vertical lines be included in the printed tables?  |
| <code>vertical</code>                    | when there is only a single predictor, should the table be printed with the predictor on the left ( <code>vertical=TRUE</code> ) or across the top ( <code>vertical=FALSE</code> )? |
| <code>nastring</code>                    | what to use for missing values in the table. Some of these are structural, e.g., risk ratios for a cell with no follow-up time.   |
| <code>conf.level</code>                  | confidence level for any confidence intervals   |
| <code>scale</code>                       | a scaling factor for printed rates  |
| <code>...</code>                         | optional arguments which will be passed to the format function; common choices would be <code>digits=2</code> or <code>nsmall=1</code> .  |

**Details**

The `pyyears` function is often used to create initial descriptions of a survival or time-to-event variable; the type of material that is often found in “table 1” of a paper. The `summary` routine prints this information out using one of pandoc table styles. A primary reason for choosing this style is that Rstudio is then able to automatically render the results in multiple formats: html, rtf, latex, etc.

If the `pyyears` call has only a single covariate then the table will have that covariate as one margin and the statistics of interest as the other. If the `pyyears` call has two predictors then those two predictors are used as margins of the table, while each cell of the table contains the statistics of interest as multiple rows within the cell. If there are more than two predictors then multiple tables are produced, in the same order as the standard R printout for an array.

The “N” entry of a `pyyears` object is the number of observations which contributed to a particular cell. When the original call includes `tcut` objects then a single observation may contribute to multiple cells.

**Value**

a copy of the object

**Notes**

The pandoc system has four table types: with or without vertical bars, and with single or multiple rows of data in each cell. This routine produces all 4 styles depending on options, but currently not all of them are recognized by the Rstudio-pandoc pipeline. (And we don’t yet see why.)

summary.survexp

*Summary function for a survexp object*

---

**Description**

Returns a list containing the values of the survival at specified times.

**Usage**

```
## S3 method for class 'survexp'
summary(object, times, scale = 1, ...)
```

**Arguments**

|        |  |
|--------|--|
| object | the result of a call to the survexp function   |
| times  | vector of times; the returned matrix will contain 1 row for each time. Missing values are not allowed.                                       |
| scale  | numeric value to rescale the survival time, e.g., if the input data to survfit were in days, scale = 365.25 would scale the output to years. |
| ...    | For future methods   |

**Details**

A primary use of this function is to retrieve survival at fixed time points, which will be properly interpolated by the function.

**Value**

a list with the following components:

|        |  |
|--------|--|
| surv   | the estimate of survival at time t.  |
| time   | the timepoints on the curve.   |
| n.risk | In expected survival each subject from the data set is matched to a hypothetical person from the parent population, matched on the characteristics of the parent population. The number at risk is the number of those hypothetical subject who are still part of the calculation. |

**Author(s)**

Terry Therneau

[survexp](#)

summary.survfit

*Summary of a Survival Curve***Description**

Returns a list containing the survival curve, confidence limits for the curve, and other information.

**Usage**

```
## S3 method for class 'survfit'
summary(object, times=, censored=FALSE, scale=1,
        extend=FALSE, rmean=getOption('survfit.rmean'), ...)
```

**Arguments**

|          |   |
|----------|---|
| object   | the result of a call to the <code>survfit</code> function.  |
| times    | vector of times; the returned matrix will contain 1 row for each time. The vector will be sorted into increasing order; missing values are not allowed. If <code>censored=T</code> , the default times vector contains all the unique times in fit, otherwise the default times vector uses only the event (death) times. |
| censored | logical value: should the censoring times be included in the output? This is ignored if the times argument is present.  |
| scale    | numeric value to rescale the survival time, e.g., if the input data to <code>survfit</code> were in days, <code>scale = 365.25</code> would scale the output to years.  |
| extend   | logical value: if TRUE, prints information for all specified times, even if there are no subjects left at the end of the specified times. This is only valid if the times argument is present.  |
| rmean    | Show restricted mean: see <a href="#">print.survfit</a> for details   |
| ...      | for future methods  |

**Value**

a list with the following components:

|           |  |
|-----------|--|
| surv      | the estimate of survival at time $t+0$ .   |
| time      | the timepoints on the curve.   |
| n.risk    | the number of subjects at risk at time $t-0$ (but see the comments on weights in the <code>survfit</code> help file).  |
| n.event   | if the times argument is missing, then this column is the number of events that occurred at time $t$ . Otherwise, it is the cumulative number of events that have occurred since the last time listed until time $t+0$ .   |
| n.entered | This is present only for counting process survival data. If the times argument is missing, this column is the number of subjects that entered at time $t$ . Otherwise, it is the cumulative number of subjects that have entered since the last time listed until time $t$ . |

|                 |  |
|-----------------|--|
| n.exit.censored | if the times argument is missing, this column is the number of subjects that left without an event at time t. Otherwise, it is the cumulative number of subjects that have left without an event since the last time listed until time t+0. This is only present for counting process survival data. |
| std.err         | the standard error of the survival value.  |
| conf.int        | level of confidence for the confidence intervals of survival.  |
| lower           | lower confidence limits for the curve.   |
| upper           | upper confidence limits for the curve.   |
| strata          | indicates stratification of curve estimation. If strata is not NULL, there are multiple curves in the result and the surv, time, n.risk, etc. vectors will contain multiple curves, pasted end to end. The levels of strata (a factor) are the labels for the curves.                                |
| call            | the statement used to create the fit object.   |
| na.action       | same as for fit, if present.   |
| table           | table of information that is returned from print.survfit function.   |
| type            | type of data censoring. Passed through from the fit object.  |

---

|      |                                 |
|------|---------------------------------|
| Surv | <i>Create a Survival Object</i> |
|------|---------------------------------|

---

Description

Create a survival object, usually used as a response variable in a model formula. Argument matching is special for this function, see Details below.

Usage

```
Surv(time, time2, event,
      type=c('right', 'left', 'interval', 'counting', 'interval2', 'mstate'),
      origin=0)
is.Surv(x)
```

Arguments

|      |   |
|------|---|
| time | for right censored data, this is the follow up time. For interval data, the first argument is the starting time for the interval. |
|------|---|

|        |   |
|--------|---|
| event  | The status indicator, normally 0=alive, 1=dead. Other choices are TRUE/FALSE (TRUE = death) or 1/2 (2=death). For interval censored data, the status indicator is 0=right censored, 1=event at time, 2=left censored, 3=interval censored. Although unusual, the event indicator can be omitted, in which case all subjects are assumed to have an event. |
| time2  | ending time of the interval for interval censored or counting process data only. Intervals are assumed to be open on the left and closed on the right, (start, end]. For counting process data, event indicates whether an event occurred at the end of the interval.   |
| type   | character string specifying the type of censoring. Possible values are "right", "left", "counting", "interval", "interval2" or "mstate".  |
| origin | for counting process data, the hazard function origin. This option was intended to be used in conjunction with a model containing time dependent strata in order to align the subjects properly when they cross over from one strata to another, but it has rarely proven useful.   |
| x      | any R object.   |

### Details

When the type argument is missing the code assumes a type based on the following rules:

- If there are two unnamed arguments, they will match time and event in that order. If there are three unnamed arguments they match time, time2 and event.
- If the event variable is a factor then type mstate is assumed. Otherwise type right if there is no time2 argument, and type counting if there is.

As a consequence the type argument will normally be omitted.

When the survival type is "mstate" then the status variable will be treated as a factor. The first level of the factor is taken to represent censoring and remaining ones a transition to the given state.

Interval censored data can be represented in two ways. For the first use type = "interval" and the codes shown above. In that usage the value of the time2 argument is ignored unless event=3. The second approach is to think of each observation as a time interval with (-infinity, t) for left censored, (t, infinity) for right censored, (t,t) for exact and (t1, t2) for an interval. This is the approach used for type = interval2. Infinite values can be represented either by actual infinity (Inf) or NA. The second form has proven to be the more useful one.

Presently, the only methods allowing interval censored data are the parametric models computed by survreg and survival curves computed by survfit; for both of these, the distinction between open and closed intervals is unimportant. The distinction is important for counting process data and the Cox model.

The function tries to distinguish between the use of 0/1 and 1/2 coding for censored data via the condition if (max(status)==2). If 1/2 coding is used and all the subjects are censored, it will guess wrong. In any questionable case it is safer to use logical coding, e.g., Surv(time, status==3) would indicate that a 3 is the code for an event.

For multi-state survival (type= "mstate") the status variable can have multiple levels. The first of these will stand for censoring, and the others for various event types, e.g., causes of death.

Surv objects can be subscripted either as a vector, e.g. x[1:3] using a single subscript, in which case the drop argument is ignored and the result will be a survival object; or as a matrix by using two subscripts. If the second subscript is missing and drop=F (the default), the result of the subscripting will be a Surv object, e.g., x[1:3, , drop=F], otherwise the result will be a matrix (or vector), in accordance with the default behavior for subscripting matrices.

**Value**

An object of class `Surv`. There are methods for `print`, `is.na`, and subscripting survival objects. `Surv` objects are implemented as a matrix of 2 or 3 columns that has further attributes. These include the type (left censored, right censored, counting process, etc.) and labels for the states for multi-state objects. Any attributes of the input arguments are also preserved in `inputAttributes`. This may be useful for other packages that have attached further information to data items such as labels; none of the routines in the `survival` package make use of these values, however.

In the case of `is.Surv`, a logical value `TRUE` if `x` inherits from class `"Surv"`, otherwise an `FALSE`.

**Examples**

```
with(lung, Surv(time, status))
Surv(heart$start, heart$stop, heart$event)
```

---

survConcordance

*Compute a concordance measure.*

---

**Description**

This function computes the concordance between a right-censored survival time and a single continuous covariate

**Usage**

```
survConcordance(formula, data, weights, subset, na.action)
survConcordance.fit(y, x, strata, weight)
```

**Arguments**

|   |   |
|---|---|
| <code>formula</code>                    | a formula with a survival time on the left and a single covariate on the right, along with an optional <code>strata()</code> term. The left hand term can also be a numeric vector. |
| <code>data</code>                       | a data frame  |
| <code>weights, subset, na.action</code> | as for <code>coxph</code>   |
| <code>x, y, strata, weight</code>       | predictor, response, strata, and weight vectors for the direct call   |

**Details**

The `survConcordance.fit` function computes the result but does no data checking whatsoever. It is intended as a hook for other packages that wish to compute concordance, and the data has already been assembled and verified.

Concordance is defined as  $\Pr(\text{agreement})$  for any two randomly chosen observations, where in this case agreement means that the observation with the shorter survival time of the two also has the

larger risk score. The predictor (or risk score) will often be the result of a Cox model or other regression.

For continuous covariates concordance is equivalent to Kendall's tau, and for logistic regression is equivalent to the area under the ROC curve. A value of 1 signifies perfect agreement, .6-.7 is a common result for survival data, .5 is an agreement that is no better than chance, and .3-.4 is the performance of some stock market analysts.

The computation involves all  $n(n-1)/2$  pairs of data points in the sample. For survival data, however, some of the pairs are incomparable. For instance a pair of times (5+, 8), the first being a censored value. We do not know whether the first survival time is greater than or less than the second. Among observations that are comparable, pairs may also be tied on survival time (but only if both are uncensored) or on the predictor. The final concordance is  $(\text{agree} + \text{tied}/2)/(\text{agree} + \text{disagree} + \text{tied})$ .

There is, unfortunately, one aspect of the formula above that is unclear. Should the count of ties include observations that are tied on survival time  $y$ , tied on the predictor  $x$ , or both? By default the concordance only counts ties in  $x$ , treating tied survival times as incomparable; this agrees with the AUC calculation used in logistic regression. The Goodman-Kruskal Gamma statistic is  $(\text{agree}-\text{disagree})/(\text{agree} + \text{disagree})$ , ignoring ties. It ranges from -1 to +1 similar to a correlation coefficient. Kendall's tau uses ties of both types. All of the components are returned in the result, however, so people can compute other combinations if interested. (If two observations have the same survival and the same  $x$ , they are counted in the tied survival time category).

The algorithm is based on a balanced binary tree, which allows the computation to be done in  $O(n \log n)$  time.

## Value

an object containing the concordance, followed by the number of pairs that agree, disagree, are tied, and are not comparable.

## See Also

`summary.coxph`

## Examples

```
survConcordance(Surv(time, status) ~age, data=lung)

options(na.action=na.exclude)
fit <- coxph(Surv(time, status) ~ ph.ecog + age + sex, lung)
survConcordance(Surv(time, status) ~predict(fit), lung)
## Not run:
  n=227 (1 observations deleted due to missing values)
Concordance= 0.6371102 , Gamma= 0.2759638
concordant discordant tied risk tied time
      12544         7117         126         28

## End(Not run)
```

survdiff

*Test Survival Curve Differences***Description**

Tests if there is a difference between two or more survival curves using the  $G^p$  family of tests, or for a single curve against a known alternative.

**Usage**

```
survdiff(formula, data, subset, na.action, rho=0)
```

**Arguments**

- |           |   |
|-----------|---|
| formula   | a formula expression as for other survival models, of the form <code>Surv(time, status) ~ predictors</code> . For a one-sample test, the predictors must consist of a single <code>offset(sp)</code> term, where <code>sp</code> is a vector giving the survival probability of each subject. For a k-sample test, each unique combination of predictors defines a subgroup. A <code>strata</code> term may be used to produce a stratified test. To cause missing values in the predictors to be treated as a separate group, rather than being omitted, use the <code>strata</code> function with its <code>na.group=T</code> argument. |
| data      | an optional data frame in which to interpret the variables occurring in the formula.  |
| subset    | expression indicating which subset of the rows of data should be used in the fit. This can be a logical vector (which is replicated to have length equal to the number of observations), a numeric vector indicating which observation numbers are to be included (or excluded if negative), or a character vector of row names to be included. All observations are included by default.   |
| na.action | a missing-data filter function. This is applied to the <code>model.frame</code> after any <code>subset</code> argument has been used. Default is <code>options()\$na.action</code> .  |
| rho       | a scalar parameter that controls the type of test.  |

**Value**

a list with components:

- |        |   |
|--------|---|
| n      | the number of subjects in each group.   |
| obs    | the weighted observed number of events in each group. If there are strata, this will be a matrix with one column per stratum. |
| exp    | the weighted expected number of events in each group. If there are strata, this will be a matrix with one column per stratum. |
| chisq  | the chisquare statistic for a test of equality.   |
| var    | the variance matrix of the test.  |
| strata | optionally, the number of subjects contained in each stratum.   |

## METHOD

This function implements the G-rho family of Harrington and Fleming (1982), with weights on each death of  $S(t)^\rho$ , where  $S(t)$  is the Kaplan-Meier estimate of survival. With  $\rho = 0$  this is the log-rank or Mantel-Haenszel test, and with  $\rho = 1$  it is equivalent to the Peto & Peto modification of the Gehan-Wilcoxon test.

If the right hand side of the formula consists only of an offset term, then a one sample test is done. To cause missing values in the predictors to be treated as a separate group, rather than being omitted, use the factor function with its exclude argument.

## Examples

```
## Two-sample test
survdif(Surv(futime, fustat) ~ rx, data=ovarian)

## Stratified 7-sample test

survdif(Surv(time, status) ~ pat.karno + strata(inst), data=lung)

## Expected survival for heart transplant patients based on
## US mortality tables
expect <- survexp(futime ~ ratetable(age=(accept.dt - birth.dt),
  sex=1, year=accept.dt, race="white"), jasa, cohort=FALSE,
  ratetable=survexp.usr)
## actual survival is much worse (no surprise)
survdif(Surv(jasa$futime, jasa$fustat) ~ offset(expect))
```

---

survexp

*Compute Expected Survival*

---

## Description

Returns either the expected survival of a cohort of subjects, or the individual expected survival for each subject.

## Usage

```
survexp(formula, data, weights, subset, na.action, rmap, times,
  method=c("ederer", "hakulinen", "conditional", "individual.h",
    "individual.s"),
  cohort=TRUE, conditional=FALSE,
  ratetable=survival::survexp.us, scale=1,
  se.fit, model=FALSE, x=FALSE, y=FALSE)
```

**Arguments**

|             |   |
|-------------|---|
| formula     | formula object. The response variable is a vector of follow-up times and is optional. The predictors consist of optional grouping variables separated by the + operator (as in <code>survfit</code> ), and is often <code>~1</code> , i.e., expected survival for the entire group.   |
| data        | data frame in which to interpret the variables named in the formula, subset and weights arguments.  |
| weights     | case weights. This is most useful when conditional survival for a known population is desired, e.g., the data set would contain all unique age/sex combinations and the weights would be the proportion of each.  |
| subset      | expression indicating a subset of the rows of data to be used in the fit.   |
| na.action   | function to filter missing data. This is applied to the model frame after subset has been applied. Default is <code>options()\$na.action</code> .   |
| rmap        | an optional list that maps data set names to the ratetable names. See the details section below.  |
| times       | vector of follow-up times at which the resulting survival curve is evaluated. If absent, the result will be reported for each unique value of the vector of times supplied in the response value of the formula.  |
| method      | computational method for the creating the survival curves. The individual option does not create a curve, rather it retrieves the predicted survival <code>individual.s</code> or cumulative hazard <code>individual.h</code> for each subject. The default is to use <code>method='ederer'</code> if the formula has no response, and <code>method='hakulinen'</code> otherwise. |
| cohort      | logical value. This argument has been superseded by the method argument. To maintain backwards compatability, if is present and FALSE, it implies <code>method='individual.s'</code> .  |
| conditional | logical value. This argument has been superseded by the method argument. To maintain backwards compatability, if it is present and TRUE it implies <code>method='conditional'</code> .  |
| ratetable   | a table of event rates, such as <code>survexp.mn</code> , or a fitted Cox model. Note the <code>survival::</code> prefix in the default argument is present to avoid the (rare) case of a user who expects the default table but just happens to have an object named "survexp.us" in their own directory.  |
| scale       | numeric value to scale the results. If <code>ratetable</code> is in units/day, <code>scale = 365.25</code> causes the output to be reported in years.   |
| se.fit      | compute the standard error of the predicted survival. This argument is currently ignored. Standard errors are not a defined concept for population rate tables (they are treated as coming from a complete census), and for Cox models the calculation is hard. Despite good intentions standard errors for this latter case have not been coded and validated.                   |
| model,x,y   | flags to control what is returned. If any of these is true, then the model frame, the model matrix, and/or the vector of response times will be returned as components of the final result, with the same names as the flag arguments.  |

**Details**

Individual expected survival is usually used in models or testing, to 'correct' for the age and sex composition of a group of subjects. For instance, assume that birth date, entry date into the study,

sex and actual survival time are all known for a group of subjects. The `survexp.us` population tables contain expected death rates based on calendar year, sex and age. Then

```
haz <- survexp(fu.time ~ 1, data=mydata,
               rmap = list(year=entry.dt, age=(birth.dt-entry.dt)),
               method='individual.h'))
```

gives for each subject the total hazard experienced up to their observed death time or last follow-up time (variable `fu.time`) This probability can be used as a rescaled time value in models:

```
glm(status ~ 1 + offset(log(haz)), family=poisson)
glm(status ~ x + offset(log(haz)), family=poisson)
```

In the first model, a test for `intercept=0` is the one sample log-rank test of whether the observed group of subjects has equivalent survival to the baseline population. The second model tests for an effect of variable `x` after adjustment for age and sex.

The `ratetable` being used may have different variable names than the user's data set, this is dealt with by the `rmap` argument. The rate table for the above calculation was `survexp.us`, a call to `summary{survexp.us}` reveals that it expects to have variables `age` = age in days, `sex`, and `year` = the date of study entry, we create them in the `rmap` line. The `sex` variable was not mapped, therefore the function assumes that it exists in `mydata` in the correct format. (Note: for factors such as `sex`, the program will match on any unique abbreviation, ignoring case.)

Cohort survival is used to produce an overall survival curve. This is then added to the Kaplan-Meier plot of the study group for visual comparison between these subjects and the population at large. There are three common methods of computing cohort survival. In the "exact method" of Ederer the cohort is not censored, for this case no response variable is required in the formula. Hakulinen recommends censoring the cohort at the anticipated censoring time of each patient, and Verheul recommends censoring the cohort at the actual observation time of each patient. The last of these is the conditional method. These are obtained by using the respective time values as the follow-up time or response in the formula.

## Value

if `cohort=TRUE` an object of class `survexp`, otherwise a vector of per-subject expected survival values. The former contains the number of subjects at risk and the expected survival for the cohort at each requested time. The cohort survival is the hypothetical survival for a cohort of subjects enrolled from the population at large, but matching the data set on the factors found in the rate table.

|-------------|----------------------------------|
| survexp.fit | <i>Compute Expected Survival</i> |
|-------------|----------------------------------|

---

Description

Compute expected survival times.

Usage

```
survexp.fit(group, x, y, times, death, ratetable)
```

Arguments

|           |  |
|-----------|--|
| group     | if there are multiple survival curves this identifies the group, otherwise it is a constant. Must be an integer.                                       |
| x         | A matrix whose columns match the dimensions of the ratetable, in the correct order.  |
| y         | the follow up time for each subject.   |
| times     | the vector of times at which a result will be computed.  |
| death     | a logical value, if TRUE the conditional survival is computed, if FALSE the cohort survival is computed. See <a href="#">survexp</a> for more details. |
| ratetable | a rate table, such as <a href="#">survexp.uswhite</a> .  |

## Details

For conditional survival  $y$  must be the time of last follow-up or death for each subject. For cohort survival it must be the potential censoring time for each subject, ignoring death.

For an exact estimate times should be a superset of  $y$ , so that each subject at risk is at risk for the entire sub-interval of time. For a large data set, however, this can use an inordinate amount of storage and/or compute time. If the times spacing is more coarse than this, an actuarial approximation is used which should, however, be extremely accurate as long as all of the returned values are  $> .99$ .

For a subgroup of size 1 and  $\text{times} > y$ , the conditional method reduces to  $\exp(-h)$  where  $h$  is the expected cumulative hazard for the subject over his/her observation time. This is used to compute individual expected survival.

## Value

A list containing the number of subjects and the expected survival(s) at each time point. If there are multiple groups, these will be matrices with one column per group.

## Warning

Most users will call the higher level routine `survexp`. Consequently, this function has very few error checks on its input arguments.

---

|                             |                                       |
|-----------------------------|---------------------------------------|
| <code>survexp.object</code> | <i>Expected Survival Curve Object</i> |
|-----------------------------|---------------------------------------|

---

## Description

This class of objects is returned by the `survexp` class of functions to represent a fitted survival curve.

Objects of this class have methods for summary, and inherit the `print`, `plot`, `points` and `lines` methods from `survfit`.

## Arguments

|                        |  |
|------------------------|--|
| <code>surv</code>      | the estimate of survival at time $t+0$ . This may be a vector or a matrix.   |
| <code>n.risk</code>    | the number of subjects who contribute at this time.  |
| <code>time</code>      | the time points at which the curve has a step.   |
| <code>std.err</code>   | the standard error of the cumulative hazard or $-\log(\text{survival})$ .  |
| <code>strata</code>    | if there are multiple curves, this component gives the number of elements of the time etc. vectors corresponding to the first curve, the second curve, and so on. The names of the elements are labels for the curves. |
| <code>method</code>    | the estimation method used. One of "Ederer", "Hakulinen", or "conditional".  |
| <code>na.action</code> | the returned value from the <code>na.action</code> function, if any. It will be used in the printout of the curve, e.g., the number of observations deleted due to missing values.                                     |
| <code>call</code>      | an image of the call that produced the object.   |

## Structure

The following components must be included in a legitimate `survfit` object.

## Subscripts

Survexp objects that contain multiple survival curves can be subscripted. This is most often used to plot a subset of the curves.

## Details

In expected survival each subject from the data set is matched to a hypothetical person from the parent population, matched on the characteristics of the parent population. The number at risk printed here is the number of those hypothetical subject who are still part of the calculation. In particular, for the Ederer method all hypotheticals are retained for all time, so `n.risk` will be a constant.

---

`survfit`

*Create survival curves*

---

## Description

This function creates survival curves from either a formula (e.g. the Kaplan-Meier), a previously fitted Cox model, or a previously fitted accelerated failure time model.

## Usage

```
survfit(formula, ...)
```

## Arguments

|                      |   |
|----------------------|---|
| <code>formula</code> | either a formula or a previously fitted model |
| <code>...</code>     | other arguments to the specific method        |

## Details

A survival curve is based on a tabulation of the number at risk and number of events at each unique death time. When time is a floating point number the definition of "unique" is subject to interpretation. The code uses `factor()` to define the set. For further details see the documentation for the appropriate method, i.e., `?survfit.formula` or `?survfit.coxph`.

A `survfit` object may contain a single curve, a set of curves, or a matrix curves. Predicted curves from a `coxph` model have one row for each stratum in the Cox model fit and one column for each specified covariate set. Curves from a multi-state model have one row for each stratum and a column for each state, the strata correspond to predictors on the right hand side of the equation. The default printing and plotting order for curves is by column, as with other matrices.

Curves can be subscripted using either a single or double subscript. If the set of curves is a matrix, as in the above, and one of the dimensions is 1 then the code allows a single subscript to be used. (That is, it is not quite as general as using a single subscript for a numeric matrix.)

**Value**

An object of class `survfit` containing one or more survival curves.

**Note**

Older releases of the code also allowed the specification for a single curve to omit the right hand of the formula, i.e., `survfit(Surv(time, status))`, in which case the formula argument is not actually a formula. Handling this case required some non-standard and fairly fragile manipulations, and this case is no longer supported.

---

|               |  |
|---------------|--|
| survfit.coxph | <i>Compute a Survival Curve from a Cox model</i> |
|---------------|--|

---

**Description**

Computes the predicted survivor function for a Cox proportional hazards model.

**Usage**

```
## S3 method for class 'coxph'
survfit(formula, newdata,
        se.fit=TRUE, conf.int=.95,
        individual=FALSE,
        type,vartype,
        conf.type=c("log","log-log","plain","none"), censor=TRUE, id,
        start.time,
        na.action=na.pass, ...)
```

**Arguments**

|            |  |
|------------|--|
| formula    | A coxph object.  |
| newdata    | a data frame with the same variable names as those that appear in the coxph formula. It is also valid to use a vector, if the data frame would consist of a single row.<br><br>The curve(s) produced will be representative of a cohort whose covariates correspond to the values in newdata. Default is the mean of the covariates used in the coxph fit.   |
| individual | This argument has been superseded by the id argument and is present only for backwards compatability. A logical value indicating whether each row of newdata represents a distinct individual (FALSE, the default), or if each row of the data frame represents different time epochs for only one individual (TRUE). In the former case the result will have one curve for each row in newdata, in the latter only a single curve will be produced. |

|                            |  |
|----------------------------|--|
| <code>conf.int</code>      | the level for a two-sided confidence interval on the survival curve(s). Default is 0.95.   |
| <code>se.fit</code>        | a logical value indicating whether standard errors should be computed. Default is TRUE.  |
| <code>type, vartype</code> | a character string specifying the type of survival curve. Possible values are "aalen", "efron", or "kalbfleisch-prentice" (only the first two characters are necessary). The default is to match the computation used in the Cox model. The Nelson-Aalen-Breslow estimate for <code>ties='breslow'</code> , the Efron estimate for <code>ties='efron'</code> and the Kalbfleisch-Prentice estimate for a discrete time model <code>ties='exact'</code> . Variance estimates are the Aalen-Link-Tsiatis, Efron, and Greenwood. The default will be the Efron estimate for <code>ties='efron'</code> and the Aalen estimate otherwise. |
| <code>conf.type</code>     | One of "none", "plain", "log" (the default), or "log-log". Only enough of the string to uniquely identify it is necessary. The first option causes confidence intervals not to be generated. The second causes the standard intervals $\text{curve} \pm k * \text{se}(\text{curve})$ , where $k$ is determined from <code>conf.int</code> . The log option calculates intervals based on the cumulative hazard or $\log(\text{survival})$ . The last option bases intervals on the log hazard or $\log(-\log(\text{survival}))$ .  |
| <code>censor</code>        | if FALSE time points at which there are no events (only censoring) are not included in the result.   |
| <code>id</code>            | optional variable name of subject identifiers. If this is present, then each group of rows with the same subject id represents the covariate path through time of a single subject, and the result will contain one curve per subject. If the coxph fit had strata then that must also be specified in <code>newdata</code> . If missing, then each individual row of <code>newdata</code> is presumed to represent a distinct subject and there will be <code>nrow(newdata)</code> times the number of strata curves in the result (one for each strata/subject combination). result.   |
| <code>start.time</code>    | optional starting time, a single numeric value. If present the returned curve contains survival after <code>start.time</code> conditional on surviving to <code>start.time</code> .  |
| <code>na.action</code>     | the <code>na.action</code> to be used on the <code>newdata</code> argument   |
| <code>...</code>           | for future methods   |

## Details

Serious thought has been given to removing the default value for `newdata`, which is to use a single "pseudo" subject with covariate values equal to the means of the data set, since the resulting curve(s) almost never make sense. It remains due to an unwarranted attachment to the option shown by some users and by other packages. Two particularly egregious examples are factor variables and interactions. Suppose one were studying interspecies transmission of a virus, and the data set has a factor variable with levels ("pig", "chicken") and about equal numbers of observations for each. The "mean" covariate level will be 1/2 – is this a flying pig? As to interactions assume data with sex coded as 0/1, ages ranging from 50 to 80, and a model with `age*sex`. The "mean" value for the `age:sex` interaction term will be about 30, a value that does not occur in the data. Users are strongly advised to use the `newdata` argument.

When the original model contains time-dependent covariates, then the path of that covariate through time needs to be specified in order to obtain a predicted curve. This requires `newdata` to contain multiple lines for each hypothetical subject which gives the covariate values, time interval, and strata for each line (a subject can change strata), along with an `id` variable which demarks which rows belong to each subject. The time interval must have the same (start, stop, status) variables as the original model: although the status variable is not used and thus can be set to a dummy value of

0 or 1, it is necessary for the variables to be recognized as a `Surv` object. Last, although predictions with a time-dependent covariate path can be useful, it is very easy to create a prediction that is senseless. Users are encouraged to seek out a text that discusses the issue in detail.

When a model contains strata but no time-dependent covariates the user of this routine has a choice. If `newdata` argument does not contain strata variables then the returned object will be a matrix of survival curves with one row for each strata in the model and one column for each row in `newdata`. (This is the historical behavior of the routine.) If `newdata` does contain strata variables, then the result will contain one curve per row of `newdata`, based on the indicated stratum of the original model. In the rare case of a model with strata by covariate interactions the strata variable must be included in `newdata`, the routine does not allow it to be omitted (predictions become too confusing). (Note that the model `Surv(time, status) ~ age*strata(sex)` expands internally to `strata(sex) + age:sex`; the sex variable is needed for the second term of the model.)

When all the coefficients are zero, the Kalbfleisch-Prentice estimator reduces to the Kaplan-Meier, the Aalen estimate to the exponential of Nelson's cumulative hazard estimate, and the Efron estimate to the Fleming-Harrington estimate of survival. The variances of the curves from a Cox model are larger than these non-parametric estimates, however, due to the variance of the coefficients.

See [survfit](#) for more details about the counts (number of events, number at risk, etc.)

The `censor` argument was fixed at `FALSE` in earlier versions of the code and not made available to the user. The default argument is sensible in most instances — and causes the familiar `+` sign to appear on plots — it is not sensible for time dependent covariates since it may lead to a large number of spurious marks.

## Value

an object of class `"survfit"`. See `survfit.object` for details. Methods defined for `survfit` objects are `print`, `plot`, `lines`, and `points`.

## Notes

If the following pair of lines is used inside of another function then the `model=TRUE` argument must be added to the `coxph` call: `fit <- coxph(...); survfit(fit)`. This is a consequence of the non-standard evaluation process used by the `model.frame` function when a formula is involved.

survfit.formula

*Compute a Survival Curve for Censored Data*

## Description

Computes an estimate of a survival curve for censored data. More multi-state data the Andersen-Johansen estimate is use, for ordinary survival either the Kaplan-Meier or Fleming-Harrington estimate is produced.

**Usage**

```
## S3 method for class 'formula'
survfit(formula, data, weights, subset, na.action,
        etype, id, istate, timefix=TRUE, ...)
```

**Arguments**

- |           |   |
|-----------|---|
| formula   | a formula object, which must have a Surv object as the response on the left of the ~ operator and, if desired, terms separated by + operators on the right. One of the terms may be a strata object. For a single survival curve the right hand side should be ~ 1. |
| data      | a data frame in which to interpret the variables named in the formula, subset and weights arguments.  |
| weights   | The weights must be nonnegative and it is strongly recommended that they be strictly positive, since zero weights are ambiguous, compared to use of the subset argument.  |
| subset    | expression saying that only a subset of the rows of the data should be used in the fit.   |
| na.action | a missing-data filter function, applied to the model frame, after any subset argument has been used. Default is options()\$na.action.   |
| etype     | a variable giving the type of event. This has been superseded by multi-state Surv objects; see example below.   |
| id        | identifies individual subjects, when a given person can have multiple lines of data.  |
| istate    | for multi-state models, identifies the initial state of each subject  |
| timefix   | process times through the aeqSurv function to eliminate potential roundoff issues.  |
| ...       | The following additional arguments are passed to internal functions called by survfit.  |
- type** a character string specifying the type of survival curve. Possible values are "kaplan-meier", "fleming-harrington" or "fh2" if a formula is given. This is ignored for competing risks or when the Turnbull estimator is used.
- error** a character string specifying the error. Possible values are "greenwood" for the Greenwood formula or "tsiatis" or "aalen" for the Tsiatis/Aalen formula, or "robust" for a robust variance. The last of these is assumed if non-integer case weights are provided.
- conf.type** One of "none", "plain", "log" (the default), or "log-log". Only enough of the string to uniquely identify it is necessary. The first option causes confidence intervals not to be generated. The second causes the standard intervals curve  $\pm k \cdot se(\text{curve})$ , where k is determined from conf.int. The log option calculates intervals based on the cumulative hazard or log(survival). The last option bases intervals on the log hazard or log(-log(survival)).
- conf.lower** a character string to specify modified lower limits to the curve, the upper limit remains unchanged. Possible values are "usual" (unmodified), "peto", and "modified". The modified lower limit is based on an "effective n" argument. The confidence bands will agree with the usual calculation at each death time, but unlike the usual bands the confidence interval becomes wider at each censored observation. The extra width is obtained

by multiplying the usual variance by a factor  $m/n$ , where  $n$  is the number currently at risk and  $m$  is the number at risk at the last death time. (The bands thus agree with the un-modified bands at each death time.) This is especially useful for survival curves with a long flat tail.

The Peto lower limit is based on the same "effective  $n$ " argument as the modified limit, but also replaces the usual Greenwood variance term with a simple approximation. It is known to be conservative.

**start.time** numeric value specifying a time to start calculating survival information. The resulting curve is the survival conditional on surviving to `start.time`.

**conf.int** the level for a two-sided confidence interval on the survival curve(s). Default is 0.95.

**se.fit** a logical value indicating whether standard errors should be computed. Default is TRUE.

**influence** a logical value indicating whether to return the infinitesimal jack-knife (influence) values for each subject. These contain the values of the derivative of each value with respect to the case weights of each subject  $i$ :  $\partial p / \partial w_i$ , evaluated at the vector of weights  $w = 1$ . The array will have dimensions (number of subjects, 1+ number of unique times, number of states); be forewarned that this can be huge. If the total number of elements is larger than the maximum integer the underlying C program can not create it.

## Details

The estimates used are the Kalbfleisch-Prentice (Kalbfleisch and Prentice, 1980, p.86) and the Tsiatis/Link/Breslow, which reduce to the Kaplan-Meier and Fleming-Harrington estimates, respectively, when the weights are unity.

The Greenwood formula for the variance is a sum of terms  $d/(n*(n-m))$ , where  $d$  is the number of deaths at a given time point,  $n$  is the sum of weights for all individuals still at risk at that time, and  $m$  is the sum of weights for the deaths at that time. The justification is based on a binomial argument when weights are all equal to one; extension to the weighted case is ad hoc. Tsiatis (1981) proposes a sum of terms  $d/(n*n)$ , based on a counting process argument which includes the weighted case.

The two variants of the F-H estimate have to do with how ties are handled. If there were 3 deaths out of 10 at risk, then the first increments the hazard by  $3/10$  and the second by  $1/10 + 1/9 + 1/8$ . For the first method  $S(t) = \exp(H)$ , where  $H$  is the Nelson-Aalen cumulative hazard estimate, whereas the `fh2` method will give results  $S(t)$  results closer to the Kaplan-Meier.

When the data set includes left censored or interval censored data (or both), then the EM approach of Turnbull is used to compute the overall curve. When the baseline method is the Kaplan-Meier, this is known to converge to the maximum likelihood estimate.

The cumulative incidence curve is an alternative to the Kaplan-Meier for competing risks data. For instance, in patients with MGUS, conversion to an overt plasma cell malignancy occurs at a nearly constant rate among those still alive. A Kaplan-Meier estimate, treating death due to other causes as censored, gives a 20 year cumulate rate of 33% for the 241 early patients of Kyle. This estimates the incidence of conversion if all other causes of death were removed, which is an unrealistic assumption given the mean starting age of 63 and a median follow up of over 21 years.

The CI estimate, on the other hand, estimates the total number of conversions that will actually occur. Because the population is older, this is much smaller than the KM, 22% at 20 years for Kyle's data. If there were no censoring, then  $CI(t)$  could very simply be computed as total number of patients with progression by time  $t$  divided by the sample size  $n$ .

**Value**

an object of class "survfit". See `survfit.object` for details. Methods defined for `survfit` objects are `print`, `plot`, `lines`, and `points`.

---

|                |  |
|----------------|--|
| survfit.matrix | <i>Create Aalen-Johansen estimates of multi-state survival from a matrix of hazards.</i> |
|----------------|--|

---

## Description

This allows one to create the Aalen-Johansen estimate of  $P$ , a matrix with one column per state and one row per time, starting with the individual hazard estimates. Each row of  $P$  will sum to 1.

## Usage

```

## S3 method for class 'matrix'
survfit(formula, p0, method = c("discrete", "matexp"), ...)

```

## Arguments

|         |   |
|---------|---|
| formula | a matrix of lists, each element of which is either NULL or a survival curve object.   |
| p0      | the initial state vector. The names of this vector are used as the names of the states in the output object. If there are multiple curves then p0 can be a matrix with one row per curve. |
| method  | use a product of discrete hazards, or a product of matrix exponentials. See details below.  |
| ...     | further arguments for other methods   |

## Details

On input the matrix should contain a set of predicted curves for each possible transition, and NULL in other positions. Each of the predictions will have been obtained from the relevant Cox model. This approach for multistate curves is easy to use but has some caveats. First, the input curves must be consistent. The routine checks as best it can, but can easily be fooled. For instance, if one were to fit two Cox models, obtain predictions for males and females from one, and for treatment A and

B from the other, this routine will create two curves but they are not meaningful. A second issue is that standard errors are not produced.

The names of the resulting states are taken from the names of the vector of initial state probabilities. If they are missing, then the dimnames of the input matrix are used, and lacking that the labels '1', '2', etc. are used.

For the usual Aalen-Johansen estimator the multiplier at each event time is the matrix of hazards  $H$  (also written as  $I + dA$ ). When using predicted survival curves from a Cox model, however, it is possible to get predicted hazards that are greater than 1, which leads to probabilities less than 0. If the method argument is not supplied and the input curves are derived from a Cox model this routine instead uses the approximation  $\expm(H-I)$  as the multiplier, which always gives valid probabilities. (This is also the standard approach for ordinary survival curves from a Cox model.)

### Value

a survfitms object

### Note

The R syntax for creating a matrix of lists is very fussy.

### Examples

```
etime <- with(mgus2, ifelse(pstat==0, futime, ptime))
event <- with(mgus2, ifelse(pstat==0, 2*death, 1))
event <- factor(event, 0:2, labels=c("censor", "pcm", "death"))

cfit1 <- coxph(Surv(etime, event=="pcm") ~ age + sex, mgus2)
cfit2 <- coxph(Surv(etime, event=="death") ~ age + sex, mgus2)

# predicted competing risk curves for a 72 year old with mspike of 1.2
# (median values), male and female.
# The survfit call is a bit faster without standard errors.
newdata <- expand.grid(sex=c("F", "M"), age=72, mspike=1.2)

AJmat <- matrix(list(), 3,3)
AJmat[1,2] <- list(survfit(cfit1, newdata, std.err=FALSE))
AJmat[1,3] <- list(survfit(cfit2, newdata, std.err=FALSE))
csurv <- survfit(AJmat, p0 =c(entry=1, PCM=0, death=0))
```

---

|                |                              |
|----------------|------------------------------|
| survfit.object | <i>Survival Curve Object</i> |
|----------------|------------------------------|

---

**Description**

This class of objects is returned by the `survfit` class of functions to represent a fitted survival curve. For a multi-state model the object has class `c('survfitms', 'survfit')`.

Objects of this class have methods for the functions `print`, `summary`, `plot`, `points` and `lines`. The `print.survfit` method does more computation than is typical for a `print` method and is documented on a separate page.

**Arguments**

|                            |   |
|----------------------------|---|
| <code>n</code>             | total number of subjects in each curve.   |
| <code>time</code>          | the time points at which the curve has a step.  |
| <code>n.risk</code>        | the number of subjects at risk at <code>t</code> .  |
| <code>n.event</code>       | the number of events that occur at time <code>t</code> .  |
| <code>n.enter</code>       | for counting process data only, the number of subjects that enter at time <code>t</code> .  |
| <code>n.censor</code>      | for counting process data only, the number of subjects who exit the risk set, without an event, at time <code>t</code> . (For right censored data, this number can be computed from the successive values of the number at risk).   |
| <code>surv</code>          | the estimate of survival at time <code>t+0</code> . This may be a vector or a matrix. The latter occurs when a set of survival curves is created from a single Cox model, in which case there is one column for each covariate set.   |
| <code>prev, p0</code>      | a multi-state survival will have the <code>prev</code> component instead of <code>surv</code> . It will be a matrix containing the estimated probability of each state at each time, one column per state. The <code>p0</code> matrix contains the initial distribution of states. (On further reflection <code>pstate= "probability in state"</code> would have been a much better label than "prevalence", but by that point too many other packages were dependent on the form of the result.) |
| <code>std.err</code>       | for a survival curve this contains standard error of the cumulative hazard or $-\log(\text{survival})$ , for a multi-state curve it contains the standard error of <code>prev</code> . This difference is a reflection of the fact that each is the natural calculation for that case.  |
| <code>cumhaz hazard</code> | optional. For a multi-state curve this is an <code>k</code> by <code>k</code> array for each time point, where <code>k</code> is the number of states.  |
| <code>upper</code>         | upper confidence limit for the survival curve or probability  |
| <code>lower</code>         | lower confidence limit for the survival curve or probability  |
| <code>strata</code>        | if there are multiple curves, this component gives the number of elements of the time etc. vectors corresponding to the first curve, the second curve, and so on. The names of the elements are labels for the curves.  |
| <code>start.time</code>    | the value specified for the <code>start.time</code> argument, if it was used in the call.   |
| <code>n.all</code>         | for counting process data, and any time that the <code>start.time</code> argument was used, this contains the total number of observations that were available. Not all may have been used in creating the curve, in which case this value will be larger than <code>n</code> above.  |

|             |  |
|-------------|--|
| conf.type   | the approximation used to compute the confidence limits.   |
| conf.int    | the level of the confidence limits, e.g. 90 or 95%.  |
| transitions | for multi-state data, the total number of transitions of each type.  |
| na.action   | the returned value from the na.action function, if any. It will be used in the printout of the curve, e.g., the number of observations deleted due to missing values.  |
| call        | an image of the call that produced the object.   |
| type        | type of survival censoring.  |
| influence   | optional, for survfitms objects only. A list with one element per stratum, each element of the list is an array indexed by subject, time, state. The time dimension will have one more element than the prev matrix, the first row is the subject's influence on the initial prevalence (just before the first time point). If there is only one curve a list is not needed. |

Structure

The following components must be included in a legitimate survfit or survfitms object.

Subscripts

Survfit objects that contain multiple survival curves can be subscripted. This is often used to plot a subset of the curves. If the surv or prev component is a matrix then the survfit object will be treated as a matrix, otherwise only a single subscript is used.

|                  |  |
|------------------|--|
| survfitcoxph.fit | <i>A direct interface to the ‘computational engine’ of survfit.coxph</i> |
|------------------|--|

---

Description

This program is mainly supplied to allow other packages to invoke the survfit.coxph function at a ‘data’ level rather than a ‘user’ level. It does no checks on the input data that is provided, which can lead to unexpected errors if that data is wrong.

Usage

```
survfitcoxph.fit(y, x, wt, x2, risk, newrisk, strata, se.fit, survtype,
vartype, varmat, id, y2, strata2, unlist=TRUE)
```

Arguments

|    |  |
|----|--|
| y  | the response variable used in the Cox model. (Missing values removed of course.) |
| x  | covariate matrix used in the Cox model   |
| wt | weight vector for the Cox model. If the model was unweighted use a vector of 1s. |

|                       |  |
|-----------------------|--|
| <code>x2</code>       | matrix describing the hypothetical subjects for which a curve is desired. Must have the same number of columns as <code>x</code> .   |
| <code>risk</code>     | the risk score $\exp(X \beta)$ from the fitted Cox model. If the model had an offset, include it in the argument to <code>exp</code> .   |
| <code>newrisk</code>  | risk scores for the hypothetical subjects  |
| <code>strata</code>   | strata variable used in the Cox model. This will be a factor.  |
| <code>se.fit</code>   | if TRUE the standard errors of the curve(s) are returned   |
| <code>survtype</code> | 1=Kalbfleisch-Prentice, 2=Nelson-Aalen, 3=Efron. It is usual to match this to the approximation for ties used in the coxph model: KP for 'exact', N-A for 'breslow' and Efron for 'efron'.   |
| <code>vartype</code>  | 1=Greenwood, 2=Aalen, 3=Efron  |
| <code>varmat</code>   | the variance matrix of the coefficients  |
| <code>id</code>       | optional; if present and not NULL this should be a vector of identifiers of length <code>nrow(x2)</code> . A non-null value signifies that <code>x2</code> contains time dependent covariates, in which case this identifies which rows of <code>x2</code> go with each subject. |
| <code>y2</code>       | survival times, for time dependent prediction. It gives the time range (time1,time2] for each row of <code>x2</code> . Note: this must be a Surv object and thus contains a status indicator, which is never used in the routine, however.                                       |
| <code>strata2</code>  | vector of strata indicators for <code>x2</code> . This must be a factor.   |
| <code>unlist</code>   | if FALSE the result will be a list with one element for each strata. Otherwise the strata are "unpacked" into the form found in a <code>survfit</code> object.   |

**Value**

a list containing nearly all the components of a `survfit` object. All that is missing is to add the confidence intervals, the type of the original model's response (as in a `coxph` object), and the class.

**Note**

The source code for for both this function and `survfit.coxph` is written using `noweb`. For complete documentation see the `inst/sourcecode.pdf` file.

survobrien

*O'Brien's Test for Association of a Single Variable with Survival***Description**

Peter O'Brien's test for association of a single variable with survival This test is proposed in Biometrics, June 1978.

**Usage**

```
survobrien(formula, data, subset, na.action, transform)
```

**Arguments**

|           |  |
|-----------|--|
| formula   | a valid formula for a cox model.   |
| data      | a data.frame in which to interpret the variables named in the formula, or in the subset and the weights argument.  |
| subset    | expression indicating which subset of the rows of data should be used in the fit. All observations are included by default.  |
| na.action | a missing-data filter function. This is applied to the model.frame after any subset argument has been used. Default is options()\$na.action.   |
| transform | the transformation function to be applied at each time point. The default is O'Brien's suggestion $\text{logit}(tr)$ where $tr = (\text{rank}(x) - 1/2) / \text{length}(x)$ is the rank shifted to the range 0-1 and $\text{logit}(x) = \log(x/(1-x))$ is the logit transform. |

**Value**

a new data frame. The response variables will be column names returned by the Surv function, i.e., "time" and "status" for simple survival data, or "start", "stop", "status" for counting process data. Each individual event time is identified by the value of the variable .strata.. Other variables retain their original names. If a predictor variable is a factor or is protected with I(), it is retained as is. Other predictor variables have been replaced with time-dependent logit scores.

The new data frame will have many more rows than the original data, approximately the original number of rows \* number of deaths/2.

**Method**

A time-dependent cox model can now be fit to the new data. The univariate statistic, as originally proposed, is equivalent to single variable score tests from the time-dependent model. This equivalence is the rationale for using the time dependent model as a multivariate extension of the original paper.

In O'Brien's method, the x variables are re-ranked at each death time. A simpler method, proposed by Prentice, ranks the data only once at the start. The results are usually similar.

**Note**

A prior version of the routine returned new time variables rather than a strata. Unfortunately, that strategy does not work if the original formula has a strata statement. This new data set will be the same size, but the coxph routine will process it slightly faster.

[survdiff](#)

## Examples

```
xx <- survobrien(Surv(futime, fustat) ~ age + factor(rx) + I(ecog.ps),
  data=ovarian)
coxph(Surv(time, status) ~ age + strata(.strata.), data=xx)
```

---

survreg

*Regression for a Parametric Survival Model*

---

## Description

Fit a parametric survival regression model. These are location-scale models for an arbitrary transform of the time variable; the most common cases use a log transformation, leading to accelerated failure time models.

## Usage

```
survreg(formula, data, weights, subset,
  na.action, dist="weibull", init=NULL, scale=0,
  control, parms=NULL, model=FALSE, x=FALSE,
  y=TRUE, robust=FALSE, score=FALSE, ...)
```

## Arguments

|           |  |
|-----------|--|
| formula   | a formula expression as for other regression models. The response is usually a survival object as returned by the <code>Surv</code> function. See the documentation for <code>Surv</code> , <code>lm</code> and <code>formula</code> for details.  |
| data      | a data frame in which to interpret the variables named in the formula, weights or the subset arguments.  |
| weights   | optional vector of case weights  |
| subset    | subset of the observations to be used in the fit   |
| na.action | a missing-data filter function, applied to the <code>model.frame</code> , after any subset argument has been used. Default is <code>options()\$na.action</code> .  |
| dist      | assumed distribution for y variable. If the argument is a character string, then it is assumed to name an element from <a href="#">survreg.distributions</a> . These include "weibull", "exponential", "gaussian", "logistic", "lognormal" and "loglogistic". Otherwise, it is assumed to be a user defined list conforming to the format described in <a href="#">survreg.distributions</a> . |
| parms     | a list of fixed parameters. For the t-distribution for instance this is the degrees of freedom; most of the distributions have no parameters.  |

|                        |  |
|------------------------|--|
| <code>init</code>      | optional vector of initial values for the parameters.  |
| <code>scale</code>     | optional fixed value for the scale. If set to $\leq 0$ then the scale is estimated.  |
| <code>control</code>   | a list of control values, in the format produced by <a href="#">survreg.control</a> . The default value is <code>survreg.control()</code>  |
| <code>model,x,y</code> | flags to control what is returned. If any of these is true, then the model frame, the model matrix, and/or the vector of response times will be returned as components of the final result, with the same names as the flag arguments. |
| <code>score</code>     | return the score vector. (This is expected to be zero upon successful convergence.)  |
| <code>robust</code>    | Use robust 'sandwich' standard errors, based on independence of individuals if there is no <code>cluster()</code> term in the formula, based on independence of clusters if there is.  |
| <code>...</code>       | other arguments which will be passed to <code>survreg.control</code> .   |

### Details

All the distributions are cast into a location-scale framework, based on chapter 2.2 of Kalbfleisch and Prentice. The resulting parameterization of the distributions is sometimes (e.g. gaussian) identical to the usual form found in statistics textbooks, but other times (e.g. Weibull) it is not. See the book for detailed formulas.

### Value

an object of class `survreg` is returned.

### Examples

```
# Fit an exponential model: the two fits are the same
survreg(Surv(futime, fustat) ~ ecog.ps + rx, ovarian, dist='weibull',
        scale=1)
survreg(Surv(futime, fustat) ~ ecog.ps + rx, ovarian,
        dist="exponential")

#
# A model with different baseline survival shapes for two groups, i.e.,
# two different scale parameters
survreg(Surv(time, status) ~ ph.ecog + age + strata(sex), lung)

# There are multiple ways to parameterize a Weibull distribution. The survreg
# function embeds it in a general location-scale family, which is a
# different parameterization than the rweibull function, and often leads
# to confusion.
# survreg's scale = 1/(rweibull shape)
# survreg's intercept = log(rweibull scale)
# For the log-likelihood all parameterizations lead to the same value.
```

```
y <- rweibull(1000, shape=2, scale=5)
survreg(Surv(y)~1, dist="weibull")

# Economists fit a model called 'tobit regression', which is a standard
# linear regression with Gaussian errors, and left censored data.
tobinfit <- survreg(Surv(durable, durable>0, type='left') ~ age + quant,
  data=tobin, dist='gaussian')
```

---

`survreg.control`*Package options for survreg and coxph*

---

## Description

This functions checks and packages the fitting options for [survreg](#)

## Usage

```
survreg.control(maxiter=30, rel.tolerance=1e-09,
  toler.chol=1e-10, iter.max, debug=0, outer.max=10)
```

## Arguments

|                            |  |
|----------------------------|--|
| <code>maxiter</code>       | maximum number of iterations                                       |
| <code>rel.tolerance</code> | relative tolerance to declare convergence                          |
| <code>toler.chol</code>    | Tolerance to declare Cholesky decomposition singular               |
| <code>iter.max</code>      | same as <code>maxiter</code>                                       |
| <code>debug</code>         | print debugging information  |
| <code>outer.max</code>     | maximum number of outer iterations for choosing penalty parameters |

## Value

A list with the same elements as the input

survreg.distributions *Parametric Survival Distributions*

---

**Description**

List of distributions for accelerated failure models. These are location-scale families for some transformation of time. The entry describes the cdf  $F$  and density  $f$  of a canonical member of the family.

**Usage**

```
survreg.distributions
```

**Format**

There are two basic formats, the first defines a distribution de novo, the second defines a new distribution in terms of an old one.

|                          |  |
|--------------------------|--|
| name:                    | name of distribution   |
| variance:                | function(parms) returning the variance (currently unused)  |
| init(x,weights,...):     | Function returning an initial estimate of the mean and variance (used for initial values in the iteration) |
| density(x,parms):        | Function returning a matrix with columns $F$ , $1 - F$ , $f$ , $f'/f$ , $f''/f$                            |
| quantile(p,parms):       | Quantile function  |
| scale:                   | Optional fixed value for the scale parameter   |
| parms:                   | Vector of default values and names for any additional parameters   |
| deviance(y,scale,parms): | Function returning the deviance for a saturated model; used only for deviance residuals.                   |

and to define one distribution in terms of another

|         |  |
|---------|--|
| name:   | name of distribution                     |
| dist:   | name of parent distribution              |
| trans:  | transformation (eg log)                  |
| dtrans: | derivative of transformation             |
| itrans: | inverse of transformation                |
| scale:  | Optional fixed value for scale parameter |

**Details**

There are four basic distributions: extreme, gaussian, logistic and t. The last three are parametrised in the same way as the distributions already present in R. The extreme value cdf is

$$F = 1 - e^{-e^t}.$$

When the logarithm of survival time has one of the first three distributions we obtain respectively weibull, lognormal, and loglogistic. The location-scale parameterization of a Weibull distribution found in survreg is not the same as the parameterization of [rweibull](#).

The other predefined distributions are defined in terms of these. The exponential and rayleigh distributions are Weibull distributions with fixed scale of 1 and 0.5 respectively, and loggaussian is a synonym for lognormal.

For speed parts of the three most commonly used distributions are hardcoded in C; for this reason the elements of `survreg.distributions` with names of "Extreme value", "Logistic" and "Gaussian" should not be modified. (The order of these in the list is not important, recognition is by name.) As an alternative to modifying `survreg.distributions` a new distribution can be specified as a separate list. This is the preferred method of addition and is illustrated below.

### Examples

```
# time transformation
survreg(Surv(time, status) ~ ph.ecog + sex, dist='weibull', data=lung)
# change the transformation to work in years
# intercept changes by log(365), everything else stays the same
my.weibull <- survreg.distributions$weibull
my.weibull$trans <- function(y) log(y/365)
my.weibull$itrans <- function(y) 365*exp(y)
survreg(Surv(time, status) ~ ph.ecog + sex, lung, dist=my.weibull)

# Weibull parametrisation
y<-rweibull(1000, shape=2, scale=5)
survreg(Surv(y)~1, dist="weibull")
# survreg scale parameter maps to 1/shape, linear predictor to log(scale)

# Cauchy fit
mycauchy <- list(name='Cauchy',
  init= function(x, weights, ...)
    c(median(x), mad(x)),
  density= function(x, parms) {
    temp <- 1/(1 + x^2)
    cbind(.5 + atan(x)/pi, .5+ atan(-x)/pi,
      temp/pi, -2 *x*temp, 2*temp*(4*x^2*temp -1))
  },
  quantile= function(p, parms) tan((p-.5)*pi),
  deviance= function(...) stop('deviance residuals not defined')
)
survreg(Surv(log(time), status) ~ ph.ecog + sex, lung, dist=mycauchy)
```

---

survreg.object

*Parametric Survival Model Object*

---

### Description

This class of objects is returned by the `survreg` function to represent a fitted parametric survival model. Objects of this class have methods for the functions `print`, `summary`, `predict`, and `residuals`.

COMPONENTS

The following components must be included in a legitimate survreg object.

- coefficients** the coefficients of the linear.predictors, which multiply the columns of the model matrix. It does not include the estimate of error (sigma). The names of the coefficients are the names of the single-degree-of-freedom effects (the columns of the model matrix). If the model is over-determined there will be missing values in the coefficients corresponding to non-estimable coefficients.
- icoef** coefficients of the baseline model, which will contain the intercept and log(scale), or multiple scale factors for a stratified model.
- var** the variance-covariance matrix for the parameters, including the log(scale) parameter(s).
- loglik** a vector of length 2, containing the log-likelihood for the baseline and full models.
- iter** the number of iterations required
- linear.predictors** the linear predictor for each subject.
- df** the degrees of freedom for the final model. For a penalized model this will be a vector with one element per term.
- scale** the scale factor(s), with length equal to the number of strata.
- idf** degrees of freedom for the initial model.
- means** a vector of the column means of the coefficient matrix.
- dist** the distribution used in the fit.
- weights** included for a weighted fit.

The object will also have the following components found in other model results (some are optional): linear predictors, weights, x, y, model, call, terms and formula. See lm.

|--------------|--------------------------------------|
| survregDtest | <i>Verify a survreg distribution</i> |
|--------------|--------------------------------------|

---

Description

This routine is called by survreg to verify that a distribution object is valid.

Usage

```
survregDtest(dlist, verbose = F)
```

Arguments

- dlist the list describing a survival distribution
- verbose return a simple TRUE/FALSE from the test for validity (the default), or a verbose description of any flaws.

**Details**

If the survreg function rejects your user-supplied distribution as invalid, this routine will tell you why it did so.

**Value**

TRUE if the distribution object passes the tests, and either FALSE or a vector of character strings if not.

**Examples**

```
# An invalid distribution (it should have "init =" on line 2)
# survreg would give an error message
mycauchy <- list(name='Cauchy',
  init<- function(x, weights, ...)
    c(median(x), mad(x)),
  density= function(x, parms) {
    temp <- 1/(1 + x^2)
    cbind(.5 + atan(temp)/pi, .5+ atan(-temp)/pi,
      temp/pi, -2 *x*temp, 2*temp^2*(4*x^2*temp -1))
  },
  quantile= function(p, parms) tan((p-.5)*pi),
  deviance= function(...) stop('deviance residuals not defined')
)

survregDtest(mycauchy, TRUE)
```

---

survSplit

*Split a survival data set at specified times*

---

**Description**

Given a survival data set and a set of specified cut times, split each record into multiple subrecords at each cut time. The new data set will be in ‘counting process’ format, with a start time, stop time, and event status for each record.

**Usage**

```
survSplit(formula, data, subset, na.action=na.pass,
  cut, start="tstart", id, zero=0, episode,
  end="tstop", event="event")
```

**Arguments**

|                   |  |
|-------------------|--|
| formula           | a model formula  |
| data              | a data frame   |
| subset, na.action | rows of the data to be retained  |
| cut               | the vector of timepoints to cut at   |
| start             | character string with the name of a start time variable (will be created if needed)  |
| id                | character string with the name of new id variable to create (optional). This can be useful if the data set does not already contain an identifier. |
| zero              | If start doesn't already exist, this is the time that the original records start.  |
| episode           | character string with the name of new episode variable (optional)  |
| end               | character string with the name of event time variable  |
| event             | character string with the name of censoring indicator  |

**Details**

Each interval in the original data is cut at the given points; if an original row were (15, 60] with a cut vector of (10,30, 40) the resulting data set would have intervals of (15,30], (30,40] and (40, 60].

Each row in the final data set will lie completely within one of the cut intervals. Which interval for each row of the output is shown by the episode variable, where 1= less than the first cutpoint, 2= between the first and the second, etc. For the example above the values would be 2, 3, and 4.

The routine will normally be called with a formula as the first argument. The right hand side of the formula can be used to delimit variables that should be retained; normally one will use `~ .` as a shorthand to retain them all. When called in this way the routine will try to retain variable names, e.g. `Surv(adam, joe, fred)~.` will result in a data set with those same variable names for `tstart`, `end`, and `event` options rather than the defaults. Any user specified values for these options will be used if they are present, of course. However, the routine is not sophisticated; it only does this substitution for simple names. A call of `Surv(time, stat==2)` for instance will result in use of the 'event' argument for that variable name. The `end` and `event` arguments are required if there is no formula.

Rows of data with a missing time or status are copied across unchanged, unless the `na.action` argument is changed from its default value of `na.pass`. But in the latter case any row that is missing for any variable will be removed, which is rarely what is desired.

**Value**

New, longer, data frame.

**See Also**

**Examples**

```
fit1 <- coxph(Surv(time, status) ~ karno + age + trt, veteran)
plot(cox.zph(fit1)[1])
# a cox.zph plot of the data suggests that the effect of Karnofsky score
# begins to diminish by 60 days and has faded away by 120 days.
# Fit a model with separate coefficients for the three intervals.
#
```

```

vet2 <- survSplit(Surv(time, status) ~., veteran,
                  cut=c(60, 120), episode ="timegroup")
fit2 <- coxph(Surv(tstart, time, status) ~ karno* strata(timegroup) +
              age + trt, data= vet2)
c(overall= coef(fit1)[1],
  t0_60   = coef(fit2)[1],
  t60_120= sum(coef(fit2)[c(1,4)]),
  t120    = sum(coef(fit2)[c(1,5)]))

```

tcut

*Factors for person-year calculations*

## Description

Attaches categories for person-year calculations to a variable without losing the underlying continuous representation

## Usage

```

tcut(x, breaks, labels, scale=1)
## S3 method for class 'tcut'
levels(x)

```

## Arguments

|        |   |
|--------|---|
| x      | numeric/date variable                                 |
| breaks | breaks between categories, which are right-continuous |
| labels | labels for categories                                 |
| scale  | Multiply x and breaks by this.                        |

## Value

An object of class tcut

## See Also

[cut](#), [pyears](#)

## Examples

```

mdy.date <- function(m,d,y)
  as.Date(paste(ifelse(y<100, y+1900, y), m, d, sep='/'))
temp1 <- mdy.date(6,6,36)
temp2 <- mdy.date(6,6,55)# Now compare the results from person-years
#
temp.age <- tcut(temp2-temp1, floor(c(-1, (18:31 * 365.24))),
labels=c('0-18', paste(18:30, 19:31, sep='-')))
temp.yr <- tcut(temp2, mdy.date(1,1,1954:1965), labels=1954:1964)
temp.time <- 3700 #total days of fu
py1 <- pyears(temp.time ~ temp.age + temp.yr, scale=1) #output in days
py1

```

tmerge

*Time based merge for survival data***Description**

A common task in survival analysis is the creation of start,stop data sets which have multiple intervals for each subject, along with the covariate values that apply over that interval. This function aids in the creation of such data sets.

**Usage**

```
tmerge(data1, data2, id,..., tstart, tstop, options)
```

**Arguments**

|         |   |
|---------|---|
| data1   | the primary data set, to which new variables and/or observation will be added   |
| data2   | second data set in which the other arguments will be found  |
| id      | subject identifier  |
| ...     | operations that add new variables or intervals, see below   |
| tstart  | optional variable to define the valid time range for each subject, only used on an initial call                         |
| tstop   | optional variable to define the valid time range for each subject, only used on an initial call                         |
| options | a list of options. Valid ones are idname, tstartname, tstopname, delay, na.rm, and tdcstart. See the explanation below. |

**Details**

The program is often run in multiple passes, the first of which defines the basic structure, and subsequent ones that add new variables to that structure. For a more complete explanation of how this routine works refer to the vignette on time-dependent variables.

There are 4 types of optional arguments: a time dependent covariate (tdc), cumulative count (cumtdc), event (event) or cumulative event (cumevent). Time dependent covariates change their values before an event, events are outcomes.

- `newname = tdc(y, x)` A new time dependent covariate variable will created. The argument `y` is assumed to be on the scale of the start and end time, and each instance describes the occurrence of a "condition" at that time. The second argument `x` is optional. In the case where `x` is missing the count variable starts at 0 for each subject and becomes 1 at the time of the event. If `x` is present the value of the time dependent covariate is initialized to the `tdcstart` option and is reset to the value of `x` at each observation. If the option `na.rm=TRUE` missing values of `x` are first removed.
- `newname = cumtdc(y,x)` Similar to `tdc`, except that the event count is accumulated over time for each subject.
- `newname = event(y,x)` Mark an event at time `y`. In the usual case that `x` is missing the new 0/1 variable will be similar to the 0/1 status variable of a survival time.
- `newname = cumevent(y,x)` Cumulative events.

The function adds three new variables to the output data set: `tstart`, `tstop`, and `id`. The `options` argument can be used to change these names. The `na.rm` option affects creation of time-dependent covariates. Should a data row in `data2` that has a missing value for the variable be ignored (`na.rm=FALSE`, default) or should it generate an observation with a value of NA? The default value leads to "last value carried forward" behavior. The `delay` option causes a time-dependent covariate's new value to be delayed, see the vignette for an example.

### Value

a data frame with two extra attributes `tname` and `tcount`. The first contains the names of the key variables; its persistence from call to call allows the user to avoid constantly reentering the `options` argument. The `tcount` variable contains counts of the match types. New time values that occur before the first interval for a subject are "early", those after the last interval for a subject are "late", and those that fall into a gap are of type "gap". All these are considered to be outside the specified time frame for the given subject. An event of this type will be discarded. A time-dependent covariate value will be applied to later intervals but will not generate a new time point in the output.

The most common type will usually be "within", for those new times that fall inside an existing interval and cause it to be split into two. Observations that fall exactly on the edge of an interval but within the (min, max] time for a subject are counted as being on a "leading" edge, "trailing" edge or "boundary". The first corresponds for instance to an occurrence at 17 for someone with an intervals of (0,15] and (17, 35]. A `tdc` at time 17 will affect this interval but an event at 17 would be ignored. An event occurrence at 15 would count in the (0,15] interval. The last case is where the main data set has touching intervals for a subject, e.g. (17, 28] and (28,35] and a new occurrence lands at the join. Events will go to the earlier interval and counts to the latter one. A last column shows the number of additions where the `id` and time point were identical.

These extra attributes are ephemeral and will be discarded if the dataframe is modified in any way. This is intentional.

### Examples

```
# The pbc data set contains baseline data and follow-up status
# for a set of subjects with primary biliary cirrhosis, while the
# pbcseq data set contains repeated laboratory values for those
# subjects.
# The first data set contains data on 312 subjects in a clinical trial plus
# 106 that agreed to be followed off protocol, the second data set has data
# only on the trial subjects.
temp <- subset(pbc, id <= 312, select=c(id:sex, stage)) # baseline data
pbc2 <- tmerge(temp, temp, id=id, endpt = event(time, status))
pbc2 <- tmerge(pbc2, pbcseq, id=id, ascites = tdc(day, ascites),
              bili = tdc(day, bili), albumin = tdc(day, albumin),
              protime = tdc(day, protime), alk.phos = tdc(day, alk.phos))

fit <- coxph(Surv(tstart, tstop, endpt==2) ~ protime + log(bili), data=pbc2)
```

tobin

*Tobin's Tobit data*

---

### Description

Economists fit a parametric censored data model called the 'tobit'. These data are from Tobin's original paper.

### Usage

```
tobin
```

### Format

A data frame with 20 observations on the following 3 variables.

**durable** Durable goods purchase

**age** Age in years

**quant** Liquidity ratio (x 1000)

### Source

J Tobin (1958), Estimation of relationships for limited dependent variables. *Econometrica* **26**, 24–36.

### Examples

```
tfit <- survreg(Surv(durable, durable>0, type='left') ~age + quant,
               data=tobin, dist='gaussian')

predict(tfit,type="response")
```

---

transplant

*Liver transplant waiting list*

---

### Description

Subjects on a liver transplant waiting list from 1990-1999, and their disposition: received a transplant, died while waiting, withdrew from the list, or censored.

### Usage

```
data("transplant")
```

## Format

A data frame with 815 observations on the following 6 variables.

age age at addition to the waiting list

sex m or f

abo blood type: A, B, AB or O

year year in which they entered the waiting list

futime time from entry to final disposition

event final disposition: censored, death, ltx or withdraw

## Details

This represents the transplant experience in a particular region, over a time period in which liver transplant became much more widely recognized as a viable treatment modality. The number of liver transplants rises over the period, but the number of subjects added to the liver transplant waiting list grew much faster. Important questions addressed by the data are the change in waiting time, who waits, and whether there was an consequent increase in deaths while on the list.

Blood type is an important consideration. Donor livers from subjects with blood type O can be used by patients with A, B, AB or O blood types, whereas an Ab liver can only be used by an AB recipient. Thus type O subjects on the waiting list are at a disadvantage, since the pool of competitors is larger for type O donor livers.

This data is of historical interest and provides a useful example of competing risks, but it has little relevance to current practice. Liver allocation policies have evolved and now depend directly on each individual patient's risk and need, assessments of which are regularly updated while a patient is on the waiting list. The overall organ shortage remains acute, however.

## References

Kim WR, Therneau TM, Benson JT, Kremers WK, Rosen CB, Gores GJ, Dickson ER. Deaths on the liver transplant waiting list: An analysis of competing risks. *Hepatology* 2006 Feb; 43(2):345-51.

## Examples

```
#since event is a factor, survfit creates competing risk curves
pfit <- survfit(Surv(futime, event) ~ abo, transplant)
pfit[,2] #time to liver transplant, by period
plot(pfit[,2], mark.time=FALSE, col=1:4, lwd=2, xmax=735,
      xscale=30.5, xlab="Months", ylab="Fraction transplanted",
      xaxt = 'n')
temp <- c(0, 6, 12, 18, 24)
axis(1, temp, temp)
legend(450, .35, levels(transplant$abo), lty=1, col=1:4, lwd=2, bty='n')

# competing risks for type O
plot(pfit[4,], xscale=30.5, xmax=735, col=1:3, lwd=2)
legend(450, .4, c("Death", "Transplant", "Withdrawal"), col=1:3, lwd=2)
```

|-------------------|--|
| untangle.specials | <i>Help Process the ‘specials’ Argument of the ‘terms’ Function.</i> |
|-------------------|--|

---

**Description**

Given a terms structure and a desired special name, this returns an index appropriate for subscripting the terms structure and another appropriate for the data frame.

**Usage**

```
untangle.specials(tt, special, order=1)
```

**Arguments**

- |         |   |
|---------|---|
| tt      | a terms object.   |
| special | the name of a special function, presumably used in the terms object.                                  |
| order   | the order of the desired terms. If set to 2, interactions with the special function will be included. |

**Value**

- a list with two components:
- |       |  |
|-------|--|
| vars  | a vector of variable names, as would be found in the data frame, of the specials.  |
| terms | a numeric vector, suitable for subscripting the terms structure, that indexes the terms in the expanded model formula which involve the special. |

**Examples**

```
formula<-Surv(tt,ss)~x+z*strata(id)
tms<-terms(formula,specials="strata")
## the specials attribute
attr(tms,"specials")
## main effects
untangle.specials(tms,"strata")
## and interactions
untangle.specials(tms,"strata",order=1:2)
```

|--------|--------------------------------|
| uspop2 | <i>Projected US Population</i> |
|--------|--------------------------------|

---

**Description**

US population by age and sex, for 2000 through 2020

**Usage**

```
data(uspop2)
```

**Format**

The data is a matrix with dimensions age, sex, and calendar year. Age goes from 0 through 100, where the value for age 100 is the total for all ages of 100 or greater.

**Details**

This data is often used as a "standardized" population for epidemiology studies.

**Source**

NP2008\_D1: Projected Population by Single Year of Age, Sex, Race, and Hispanic Origin for the United States: July 1, 2000 to July 1, 2050, [www.census.gov/population/projections](http://www.census.gov/population/projections).

**See Also**
